Rousseau's *Essai sur l'origine des langues* mixes in a paradoxical way favorite topics of the 18th century and passionate – but also hesitating – intuitions about the politics of language.

The *Discours sur l'origine de l'inégalité* (1755) stresses the *embarrassments* of the question of the origin of language (*see* **Origin of Language Debate**), in a manner reminiscent of Frain du Tremblay (*Traité des langues*, 1703). Two types of conclusions were deduced: (a) this question is unsolvable and the efforts of such a great mind are typically vain (Kant; *see* **Kant, Immanuel (1724–1804)**; Nietzsche, etc); (b) there is an absolute solidarity between language and society, from which some authors will infer a sort of linguistic revelation related to a fixed political order.

According to Rousseau, the *Essai sur l'origine des langues* was 'a fragment of the *Discours sur l'inégalité*, cut out for being too long and irrelevant.' In so far as the chapters of the *Essai* dealing with the 'politics of language' offer ideas differing from the *Discours*, it has been supposed that they give an earlier, immature state of Rousseau's thinking. The contrary was also argued: the passage 'cut out' would in fact be dealing with the polemic which opposed to Rameau's theory of harmony Rousseau's ideas about the 'melodic' musicality of Italian, supposedly lost by French and more suitable to opera.

Rousseau's complexities or contradictions about language can be traced back to the picture of the origins given in the *Discours*. Speech arises amid 'singing and dancing – true children of love and leisure.' 'The best singer or dancer, the one who was the most beautiful, strong, skilful, or eloquent became the most esteemed; and it was the first step towards inequality, and towards vice at the same time.' An idealistic, sentimental conception of language is combined – at least in a dialectic tension – with a critical and materialistic approach associating language with the rise of social damage. Words appear in an 'order radically heterogeneous to the natural one,' endowed with an 'irreducible autonomy and originality.' Modern criticism has stressed the fact that the birth of a real language is described as it took place in historical times, and then seems to be separated from the very principle of 'origin' (Starobinski, 1990).

The link between speech, passion, and singing, based on a climatology opposing the 'northern languages' to the south, is partly borrowed from Condillac's genesis of human arts and polemically directed against his giving a prominent part to material needs (*see* **Condillac, Etienne Bonnot de (1714–1780)**). Any paradisiac beginnings of man are revoked in the *Essai*, as well as a linear development of language, which seems to have more complex origins. The ages of the 'hunters' ('bloodthirsty barbarians') and of the 'shepherds' are characterized by social division and they are supposed to prepare the rise of a real civil language appearing with agriculture. On one side, the experiment of mutual help – which required some communication – seems to participate at each level in the transcending of animal selfishness towards the accomplishment of man's social nature. On the other, the *Essai* puts a critical emphasis on the depravation of urbane language, which became a cold and courteous instrument of oppression.

The first signs were 'primitive metaphors' (*see* **Metaphor: Philosophical Theories**). This 'preromantic' topic, perhaps stemming from Vico, found its full rationality in sensualist philosophy, which sees words as dynamic and culturally signifying 'images' of the world, working on reality to give it some sense, just as

metaphors transform things and designations by adding new meanings. This paved the way for Humboldtian relativism.

The *Discours de l'inégalité* had the provocative sharpness of a reference pattern opposing ideal to reality. The *Essai* produced a more complex picture which introduced violence and economical rationality of history into the origins of language, lost some of its critical power and left the genetic problem unsolved. It is understandable that Rousseau did not publish his 'scribble' (edited posthumously in 1781), while he was personally experimenting with the failures and ambiguous nature of language, always oscillating between individual and community (*Emile*), and the regeneration of a style challenging the heat of natural communication.

Rousselot, Pierre Jean, Abbé (1846–1924)

C Puech, Université Sorbonne Nouvelle Paris III, Paris, France

© 2006 Elsevier Ltd. All rights reserved.

Rousselot was born on October 10, 1846 in Saint-Claude (Charente region) to a rural family. He received a classical education at the seminary in Richemont, then at Angoulême, and was ordained priest in 1970. He first studied Latin and Greek phonetics before turning to dialectology. Planning to complete a doctoral thesis under the supervision of Gaston Paris, he conducted surveys in the Limousin region in order to determine the borders of *langue d'oc* and *langue d'oïl* (names of the two principal groups of medieval French dialects, named after their respective words for 'yes'), but suddenly fell seriously ill. While he was being looked after, mainly by his mother, in his village, he wrote down the phonetic differences in the provincial dialect used by the various members of his family. His observations, combined with the laboratory methods of articulatory recording and acoustic analysis designed by physiologists Marey and Rosapelly, enabled him to defend his thesis in 1891: *Les modifications phonétiques du langage étudiées dans le patois d'une famille de Cellefrouin* (The phonetic modifications of language, studied in the provincial dialect spoken by a family in Cellefrouin). This work is a diachronic analysis of a variety of *oïl* as spoken by three generations of the same family, from the point of view of physiological phonetics and acoustics as far as those perspectives are relevant to the description of language change. He advocates distance from written language forms and urges dialectologists to study 'the living speech' from oral sources, to take into account such features as 'thought over,' 'instinctive,' 'ideal' and social characteristics (age, place of birth, language habits, etc.) In the first issue of the *Revue des patois gallo-romans* (1887–1892), which he co-edited with Jules Gilliéron, he published an important 'Introduction to the study of provincial dialects.' He developed his instrumental, physiological, and physical analysis of sounds in a treaty that was considerably enriched between the first manuscript, which was awarded the Volney Prize in 1896, and the last edition (*Principles of experimental phonetics*). After he taught at the Institut Catholique de Paris in 1882, Michel Bréal created for him an experimental phonetics laboratory in connection with his Chair of Comparative Literature at the Collège de France. It was only in 1922 that Rousselot obtained a teaching position, and then a chair in experimental phonetics that he was to keep only one year.

Rousselot put phonetics at the service of medicine. Together with Dr Marcel Natier he founded the Institut d'Orthophonie et de Laryngologie and the journal *La Parole* (1899–1904). He did applied research on various subjects (nose, ears, throat, larynx, stuttering, etc.). He also played a founding part in the fields of didactics and foreign language teaching. He applied his subject to orthoepy in courses given at the Alliance Française in Paris (*Centre de correction des accents étrangers*, Centre for Correction of Foreign Accents, founded in 1897) as well as in Germany, and through the publishing of the *Précis de prononciation française* (Handbook of French pronunciation), which he wrote with his nephew Fauste Laclotte. He also published a series of articles on teaching through eyesight, after a (phono-technical) method based on

He developed his instrumental, physiological, and physical analysis of sounds in a treaty that was considerably enriched between the first manuscript, which was awarded the Volney Prize in 1896, and the last edition (*Principles of experimental phonetics*). After he taught at the Institut Catholique de Paris in 1882, Michel Bréal created for him an experimental phonetics laboratory in connection with his Chair of Comparative Literature at the Collège de France. It was only in 1922 that Rousselot obtained a teaching position, and then a chair in experimental phonetics that he was to keep only one year.

Rousselot put phonetics at the service of medicine. Together with Dr Marcel Natier he founded the Institut d'Orthophonie et de Laryngologie and the journal *La Parole* (1899–1904). He did applied research on various subjects (nose, ears, throat, larynx, stuttering, etc.). He also played a founding part in the fields of didactics and foreign language teaching. He applied his subject to orthoepy in courses given at the Alliance Française in Paris (*Centre de correction des accents étrangers*, Centre for Correction of Foreign Accents, founded in 1897) as well as in Germany, and through the publishing of the *Précis de prononciation française* (Handbook of French pronunciation), which he wrote with his nephew Fauste Laclotte. He also published a series of articles on teaching through eyesight, after a (phono-technical) method based on

graphical lines recording organic activity (*La Parole*, 1901, 1902).

Although he contributed to bringing phonetics, dialectology, physics, and physiology closer together, Rousselot suffered from a lack of recognition while he was alive. He was not able to impose his methods either in the institutions for which he had conducted his research (music and drama academies, language institutes, clinics) or in higher education. When he died (in Paris, on December 16, 1924), his chair at the Collège de France was turned into a chair of histo-physiology, and most of the phonetic equipment was recovered by the Institut Catholique. His system of phonetic transcription – a direct competitor of the IPA – is still used, though by French specialists in Romance languages.

Rozwadowski, Jan Michał (1867–1935)

Z Wąsik, Adam Mickiewicz University, Poznan, Poland

© 2006 Elsevier Ltd. All rights reserved.

Jan Michał [Jordan] Rozwadowski was born in Czarna, near Tarnów (at that time Austro-Hungarian Galitia), on December 7, 1867. He died on March 14, 1935, on the train, on his return from Warsaw following a lecture in Cracow. Rozwadowski had held a Professorship in Comparative Grammar at the Jagiellonian University, and his first philological training began in Cracow with Latin and Sanskrit. In 1890, he passed an exam entitling him to teach in an elementary school, and a year later he received his Ph.D. To study linguistics, he applied for a scholarship in Germany in 1891, and again in 1894. His academic experience was enriched through the lectures, *inter alia*, of the Slavicist A. Leskien, the Germanist H. Hirt, and the phonetician E. Sievers, in Leipzig.

Rozwadowski primarily took part in seminars conducted by K. Brugmann, under whose supervision he wrote several works, including his *Habilitationsschrift* (reviewed later on by J. N. Baudouin de Courtenay), defended as *Questiones grammaticae et etymologicae*, in conjunction with a lecture on the causes of change of word meaning in the summer of 1897. As an Indo-Europeanist and Slavicist, he made his name known through numerous works relating to almost all domains of the sciences of language: descriptive phonetics, the history of sound changes and lexical borrowings, dialectology, word formation and inflection, etymology and semasiology, syntax and stylistics, and toponomastics. Some of his works dealt with historical documents of the Polish language, Polish onomastics and phonetics, and some with the localization of the homeland of Slavs and Indo-Europeans. He also discovered some regular rules in the language in general.

First, Rozwadowski formulated – in opposition to W. Wundt, who claimed that extra-linguistic objects are usually named after one unique feature – the law of bipartition stating that the base of every language product consists of two parts: a distinguishing component pertaining to its semantic aspect; and an identifying component pertaining to its formal aspect. Second, he formulated the law of quantitative development of a language, stating that the phonetic and semantic difference between pairs of linguistic products must present a constant quantity: when it diminishes under this measure, one of the products, as independent, disappears; when it augments above this quantity, a new independent product comes into existence. Finally, Rozwadowski formulated the law of disautomatization, stating that the principal cause of evolution in linguistic creativity, just as in cultural creativity, is a constant need for the refreshment of an emotional factor being used up through automatization.

Widely recognized, Rozwadowski assumed a leading role in the organization of Polish institutions. The Commission of Language of the Academy of Learning was created in 1874; later, in 1898, he became its second secretary. He then held the post of President in the years between 1908 and 1935. In the meantime, he also fulfilled the duties of vice-president, beginning in 1920, and afterwards president of the Polish Academy of Learning from 1925 to 1929. Since December 10, 1911, his name had been mentioned among the Corresponding Members of the Division of Russian Language and Philology in The Imperial St. Petersburg Academy of Sciences (between 1917 and 1925); and after 1991, the Russian Academy of Sciences. On his initiative, on May 31, 1925, the general assembly of Polish linguists gathered at Lvov and decided to launch a society, which was to meet annually and publish a journal devoted to general linguistics. Subsequently, he became elected as the first and the fourth president of the Polish Linguistic Society (1925–1928 and 1930–1931). Being at the peak of his scientific accomplishment Rozwadowski delivered a lecture before the Société de Linguistique de Paris in 1925. He had regarded linguistics as in the highest degree predestined to formulate generalizations about the mechanisms of human language and mind; subsequently, he proposed, as the best way to

Some of his works dealt with historical documents of the Polish language, Polish onomastics and phonetics, and some with the localization of the homeland of Slavs and Indo-Europeans. He also discovered some regular rules in the language in general.

First, Rozwadowski formulated – in opposition to W. Wundt, who claimed that extra-linguistic objects are usually named after one unique feature – the law of bipartition stating that the base of every language product consists of two parts: a distinguishing component pertaining to its semantic aspect; and an identifying component pertaining to its formal aspect. Second, he formulated the law of quantitative development of a language, stating that the phonetic and semantic difference between pairs of linguistic products must present a constant quantity: when it diminishes under this measure, one of the products, as independent, disappears; when it augments above this quantity, a new independent product comes into existence. Finally, Rozwadowski formulated the law of disautomatization, stating that the principal cause of evolution in linguistic creativity, just as in cultural creativity, is a constant need for the refreshment of an emotional factor being used up through automatization.

Widely recognized, Rozwadowski assumed a leading role in the organization of Polish institutions. The Commission of Language of the Academy of Learning was created in 1874; later, in 1898, he became its second secretary. He then held the post of President in the years between 1908 and 1935. In the meantime, he also fulfilled the duties of vice-president, beginning in 1920, and afterwards president of the Polish Academy of Learning from 1925 to 1929. Since December 10, 1911, his name had been mentioned among the Corresponding Members of the Division of Russian Language and Philology in The Imperial St. Petersburg Academy of Sciences (between 1917 and 1925); and after 1991, the Russian Academy of Sciences. On his initiative, on May 31, 1925, the general assembly of Polish linguists gathered at Lvov and decided to launch a society, which was to meet annually and publish a journal devoted to general linguistics. Subsequently, he became elected as the first and the fourth president of the Polish Linguistic Society (1925–1928 and 1930–1931). Being at the peak of his scientific accomplishment Rozwadowski delivered a lecture before the Société de Linguistique de Paris in 1925. He had regarded linguistics as in the highest degree predestined to formulate generalizations about the mechanisms of human language and mind; subsequently, he proposed, as the best way to

learn more about the relevant features of culture and the psychical development of man, to undertake the following three tasks which appeared to him to be urgent, namely:

1. to describe all linguistic categories and the structures of all languages of the world as constituents of general grammar;
2. to arrange systematically and notionally all possible lexical entries, derived from all languages of the world into a general lexicon, with their etymological explanations and semantic values; and
3. to collect products of 'universal literature', transmitted orally from generation to generation, as belonging to the literary tradition of mankind in general.

Dealing with semantics in its relation to grammar, Rozwadowski argued that semantics is not to be placed in the same dimension with the disciplines describing other systems of language, such as phonetics, inflection, derivation, and syntax. The same is not to be said, as he claimed, with reference to the word morphology, because every language product, constituting a unity of form and meaning, might be considered either from the point of view of morphology or from the point of view of semantics.

On the 40th anniversary of his scholarly activity he was honored by a two-volume *Festschrift* (*Symbolae grammaticae in honorem Ioannis Rozwadowski*. Kraków, 1927–28); among its contributors were M. Rudnicki, J. N. Baudouin de Courtenay, H. Pedersen, A. Sommerfelt, M. Vasmer, and J. Vendryes. Important for the history of general linguistics are the following works of Rozwadowski in particular: 'Semazjologia, czyli nauka o rozwoju znaczeń wyrazów. Jej stan obecny, zasady i zadania'. *Eos 9*, 1903, 17–111; *Wortbildung und Wortbedeutung*, 1904; *O zjawiskach i rozwoju jezyka*, 1921; *Studia nad nazwami wód słowiańskich*, 1948. Most of his monumental publications have been edited in the form of 'Selected writings' (*Wybór pism*, 1–3, 1950–1960).

An ongoing debate in historical linguistics revolves around the general question of borrowability: are there constraints that bar certain kinds of linguistic features from being transferred from one language to another in language contact situations? Historical linguists are in general agreement that the most common, and most easily identified, interference features are words. There is also general agreement that new phonological, morphological, and syntactic rules can enter a language as a side effect of lexical borrowing. For instance, the inherited English stress rule was simple: stress the first syllable in the word. Massive lexical borrowing from French after the Norman Conquest of 1066 destroyed this simple rule for the lexicon as a whole, replacing it, on one account, with a complex rule that is supposed to account for both native and borrowed English words: stress the penultimate vowel in the word if the final vowel is lax and is followed by no more than one consonant, but stress the last vowel in the word if that vowel is tense and/or is followed by more than one consonant (Chomsky and Halle, 1968: 70). But those who believe in the existence of this rule do not believe that the rule itself was borrowed from French, because French has no such stress rule; instead, those who accept(ed) Chomsky and Halle's English stress rule would argue that it was abstracted by English speakers from the lexicon as enriched by thousands of French loanwords.

Similarly, English speakers who pluralize the borrowed noun phrases *poet laureate* and *court martial*

learn more about the relevant features of culture and the psychical development of man, to undertake the following three tasks which appeared to him to be urgent, namely:

1. to describe all linguistic categories and the structures of all languages of the world as constituents of general grammar;
2. to arrange systematically and notionally all possible lexical entries, derived from all languages of the world into a general lexicon, with their etymological explanations and semantic values; and
3. to collect products of 'universal literature', transmitted orally from generation to generation, as belonging to the literary tradition of mankind in general.

Dealing with semantics in its relation to grammar, Rozwadowski argued that semantics is not to be placed in the same dimension with the disciplines describing other systems of language, such as phonetics, inflection, derivation, and syntax. The same is not to be said, as he claimed, with reference to the word morphology, because every language product, constituting a unity of form and meaning, might be considered either from the point of view of morphology or from the point of view of semantics.

An ongoing debate in historical linguistics revolves around the general question of borrowability: are there constraints that bar certain kinds of linguistic features from being transferred from one language to another in language contact situations? Historical linguists are in general agreement that the most common, and most easily identified, interference features are words. There is also general agreement that new phonological, morphological, and syntactic rules can enter a language as a side effect of lexical borrowing. For instance, the inherited English stress rule was simple: stress the first syllable in the word. Massive lexical borrowing from French after the Norman Conquest of 1066 destroyed this simple rule for the lexicon as a whole, replacing it, on one account, with a complex rule that is supposed to account for both native and borrowed English words: stress the penultimate vowel in the word if the final vowel is lax and is followed by no more than one consonant, but stress the last vowel in the word if that vowel is tense and/or is followed by more than one consonant (Chomsky and Halle, 1968: 70). But those who believe in the existence of this rule do not believe that the rule itself was borrowed from French, because French has no such stress rule; instead, those who accept(ed) Chomsky and Halle's English stress rule would argue that it was abstracted by English speakers from the lexicon as enriched by thousands of French loanwords.

Similarly, English speakers who pluralize the borrowed noun phrases *poet laureate* and *court martial*

as *poets laureate* and *courts martial*, maintaining the Noun-Adjective word order of the source language, are not applying a rule that was borrowed **as a rule** from French or Latin; they are merely using a borrowed singular phrase and a plural phrase that was borrowed separately, even if (for some speakers) such formations currently have the status of a minor rule. Occasionally we find analogic extensions that provide evidence for speakers' innovative application of a rule abstracted from borrowed lexical items. So, for instance, borrowed Latin singular forms such as *alumnus, bacillus, stimulus* and the corresponding borrowed Latin plurals *alumni, bacilli, stimuli* have given rise to a minor English rule for plural formation in foreign-seeming nouns, and this rule has been extended to words which, like *octopus*, never had such a plural etymologically. Some English dictionaries give alternate plural forms *octopuses* and *octopi* for this noun, but not the etymologically expected *octopodes*. (The word is originally a Greek compound comprising *octo-* 'eight' and *pous, pod-* 'foot'; it does not contain the Latin noun suffix *-us* that usually corresponds to a Latin plural suffix *-i*.)

For processes like these, there is no controversy. What is involved is lexical borrowing followed by the abstraction of a rule from the individually borrowed lexical items, not rule borrowing *per se*. The genesis of the rule takes place in English and the rule is created by English speakers; it does not enter English as part of the borrowing process. Before moving on to examples for which a process of rule borrowing itself might be proposed, we need a definition of 'rule.' For this purpose, the ideal definition will not be theory-internal, but will instead be maximally inclusive. Trask (1993: 245) offers a definition that works well: a rule is:

> any statement expressing a linguistically significant generalization about the grammatical facts of a particular language, especially when formulated within the formalism of some particular formal description . . .

This definition covers not only traditional generative rewrite rules but also lexical generalizations, Optimality Theory 'constraints,' and other generalizations that typically lack arrows in graphic representations. The topic of this article is thus language change through the transfer of generalizations from one language to another.

A slightly less obvious example is found in Asia Minor Greek, which has borrowed massively from Turkish in all grammatical subsystems – lexicon, phonology, morphology, syntax, and (though the most comprehensive source of information, Dawkins, 1916, does not provide many examples) lexical semantics. The most-affected Greek dialects have a vowel-harmony rule that matches the Turkish rule closely, applying both to Turkish loanwords and to native Greek vocabulary. This could easily be another instance of a rule abstracted from borrowed lexicon and then extended to native words, analogous to (but more systematic than) the analogically extended Latin-origin English plurals in *-i*. But the picture is complicated by the fact that the vowel harmony rule is inconsistently applied, even in Turkish loanwords: the word *ǰuván-us* 'a youth' is a Turkish loanword (though ultimately it comes from Persian), and its plural in Asia Minor Greek is *ǰuván-iri*. This plural form would violate the Turkish vowel harmony rule, according to which (among other things) a suffix-initial vowel must agree in the feature [back] with the last vowel of the stem (Dawkins, 1916: 47, and see also the discussion in Thomason and Kaufman, 1988: 218). Elsewhere, however, the same dialects contrast front-vowel and back-vowel plural suffixes in native vocabulary, e.g., *kléfč-iri* 'thieves' vs. *ártup-uri* 'men', as well as in borrowed Turkish words. Inconsistencies of this type suggest that bilingual Greek speakers might possibly have borrowed the rule itself, independent of the loanwords that would have provided evidence for it. (The relevant speakers would presumably have been primarily members of the Greek speech community, because speakers with Turkish as their first language were much less likely to know Greek than vice versa.) Dawkins (1916: 68) makes an observation that hints at manipulation, probably unconscious, by bilinguals who regularly spoke Turkish in addition to Greek:

> The fullness with which the vowel harmony is observed clearly depends on how far the individual speaker is accustomed to talk Turkish and has the Turkish ear for these distinctions . . . It [is] more or less prevalent and thorough in proportion as more or less Turkish is spoken alongside of the Greek dialect.

A search for cases of rule borrowing turns up all too many indeterminate examples for which, as with vowel harmony in Asia Minor Greek, a case could be made for or against a process of rule borrowing. One type of indeterminacy is delayed-action syntactic change that ultimately, but not immediately, results from the borrowing of a grammatical morpheme. An especially clear example is the ongoing change in noun-phrase coordination in Siberian Yupik (Menovščikov, 1969: 128, and see also Thomason and Kaufman, 1988: 55–56). The starting point was the Yupik suffixal construction, with the comitative suffix *-łju* 'with' ([1a] below). Then the conjunction *inkam* 'and' was borrowed by Yupik speakers from the Paleosiberian language Chukchi and used in double-marked coordinate constructions (1b). Finally,

the native Yupik suffixes were dropped and NP coordination was expressed solely by the borrowed conjunction (1c) (all three sentences in example 1 mean 'on the tundra live birds and beasts').

(1a)	Nunivaɣmi	kijaχtaqut	tɨɣiɣat-ɬju	qawaɣɛt-ɬju.
	on.the.tundra	*live*	*beasts*-COM	*birds*-COM
(1b)	Nunivaɣmi	kijaχtaqut	tɨɣiɣat-ɬju	ɨnkam	qawaɣɛt-ɬju.
(1c)	Nunivaɣmi	kijaχtaqut	tɨɣiɣat	ɨnkam	qawaɣɛt.

But the historical sequence of events described here is inferred, not actually attested: Menovščikov found all three constructions in use in Siberian Yupik. The hypothesized sequence is of a common type, with double marking – here, the comitative suffixes on the nouns plus the borrowed coordinate conjunction – as a transitional stage between the original construction and the final construction containing only the innovative form (regardless of whether the innovation is expressed by native or borrowed material). Menovščikov does not, unfortunately, say which speakers used which variants (so that we cannot know whether, for instance, the oldest speakers used only constructions like [1a] and the youngest speakers only constructions like [1c]), but it still seems reasonable to posit a historical transition corresponding to (1a)–(1c).

The important point in the present context, however, is that the borrowed conjunction arguably had at first only a minor impact on the language's syntactic structure, when it was inserted into coordinate NPs as in (1b). The more significant structural change, abandonment of the comitative suffixes entirely, happened some time after the initial borrowing: that is, even if the historical transition was not sharply marked by a temporal separation between the three variants in (1), constructions like (1c) surely appeared later than constructions like (1b). But in that case, the end-stage rule – NP coordination via conjunction alone – was not itself borrowed from Chukchi; only the lexical item, with part but not all of its structural baggage, was borrowed. Even if Yupik speakers moved to the stage represented by (1c) as a result of continuing fluent use of Chukchi, we still cannot prove that the rule itself was borrowed.

Comparable examples are reported from other contact situations, for instance Pipil (a Uto-Aztecan language closely related to Nahuatl) in contact with Spanish in El Salvador, as reported by Harris and Campbell (1995: 147–149, citing Campbell, 1987, 1985). In particular, new relative clause constructions have been innovated in Pipil that make use of the relative marker *ke*, a borrowing from the Spanish relative marker *que*. But since the Pipil examples, like the Siberian Yupik example, begin with lexical borrowing, they cannot be considered indisputable instances of rule borrowing.

Another type of indeterminate example is one in which a rule is lost, not gained, under the influence of another language that lacks the rule. For instance, just as the Indo-European language Asia Minor Greek (partially) adopted a vowel harmony rule under the influence of Turkish, so certain dialects of the Turkic language Uzbek lost their inherited vowel harmony rule under the influence of Indo-European, specifically the Iranian language Tadzhik (Menges, 1945; Comrie, 1981: 65–66). But although this change obviously alters the phonological rule system of the relevant Uzbek dialects, it is not evident that 'rule deletion' is a plausible candidate for a borrowed rule. Examples like these, then, will also not provide evidence that rule borrowing is possible.

Yet another type of contact-induced change that is problematic for claims of rule borrowing is one in which, although the receiving language does change significantly under the influence of the source language, both of the resulting constructions existed in the receiving language before the source language influenced it. In such cases, the change is in the frequency and/or the distribution of a pre-existing construction; it is not a case of adopting a completely new rule. Asia Minor Greek again offers an example. In the most-affected dialects, the inherited Greek definite article has been almost entirely lost, but it is retained in the accusative case, the only place in Turkish grammar in which definiteness is expressed morphologically (Dawkins, 1916: 46, 87). This dramatic alteration in the morphosyntax of the Greek article is certainly due to Turkish influence; it cannot be coincidence that the article has come to be used always and only where Turkish employs an accusative case suffix, namely, to mark a definite object. It is also evident that what has been borrowed into Greek is the pattern of definiteness marking, because there is no borrowed Turkish morpheme and Greek retains its inherited morphosyntactic means of expressing definiteness. Still, from the viewpoint of Greek structure, the change is in frequency (much reduced) and distribution (greatly restricted) of article usage. Skeptics who prefer to believe that rule borrowing is impossible will therefore reject examples of this sort on the grounds that no entirely new category has appeared in Greek.

A final type of change that is indeterminate from the perspective of rule borrowing is a process through which the receiving language does indeed get a new rule as a result of influence from the source language, but the new rule is not identical to the source-language rule. The question here is whether it is reasonable to talk about rule borrowing when (in effect) only part of a rule has been borrowed. Interference in Ethiopic Semitic languages from Cushitic languages

whose speakers shifted in large numbers to Semitic provide two relevant instances of morphosyntactic borrowing. The Semitic languages that were most heavily influenced by Cushitic have replaced the inherited Semitic rules for expressing two morphosyntactic categories by Cushitic rules, but only partly. In both cases, the grammatical morphemes themselves do not change; they were and are native Semitic affixes. First, the inherited Semitic formation of the nagative perfect consisted of a verbal prefix; Cushitic, in sharp contrast, expresses the negative perfect by means of a verbal suffix. Ethiopic Semitic uses a prefix-Verb-suffix construction, combining the Semitic prefix with a copy as a suffix. The resulting construction is neither purely Semitic nor purely Cushitic. The addition of the suffix to the negative perfect construction is obviously due to Cushitic influence (and this analysis is supported by the existence of a wide range of Cushitic features introduced into Ethiopic Semitic), but the end result is not identical to the equivalent Cushitic construction. Second, the inherited Semitic formation of the causative also consists of a verbal prefix. The relevant Cushitic languages form the causative with a doubled verbal suffix. Ethiopic Semitic forms the causative with a doubled prefix – maintaining the placement of the causative affix but adopting the Cushitic pattern of doubling the affix.

Examples of this general type, where the end result of interference (especially in typologically congruent grammatical subsystems) differs both from the original receiving-language structure and from the corresponding source-language structure, are easy to find in phonology. One striking example is the development of a stress pattern, in a dialect of Croatian spoken near the Hungarian border, that is unique in all of Serbo-Croatian. According to Pavle Ivić (1964), the fixed penultimate stress rule of this dialect arose when Hungarian speakers shifted to the local Croatian dialect and failed to acquire the complex prosodic system, including its free (phonemic) stress, Instead, they apparently assumed that stress was fixed, as it is in Hungarian. But, realizing that it was not fixed on the first syllable, as in the Hungarian rule, they settled on a kind of average stress placement, on the penult. As in the Ethiopic Semitic example, here too there is no doubt that interference brought about the change; but the result, though clearly the adoption of a rule, is not the adoption of the same rule as in the source language.

All these indeterminate examples provide a rather clear indication of what sort of example would be a **non**controversial instance of rule borrowing. The ideal example would involve no lexical transfer – that is, although there might be lexical transfer from the same source language to the same receiving language, borrowed morphemes would be unconnected to the proposed transferred rule. In addition, the proposed rule borrowing should result in identical rules in source and receiving language. Fortunately, the ideal case is not hard to find.

There are two main types of contact-induced structural change that frequently involve little or no lexical transfer. First, in cases of language shift, the receiving language is altered as a result of imperfect learning of its structures by shifting speakers; in such a case, especially if the shifting group has lower social, economic, and/or political status than the original target-language speech community, lexical transfer may be minimal. In any case, unless the shifting group is especially prestigious, phonological and syntactic interference features will predominate. By contrast, when imperfect learning is not a factor, i.e., when the initiators of the changes are fluent bilinguals in the source and receiving languages, lexical borrowing is (almost?) always by far the most common type of interference. (For discussion of this distinction, see Thomason and Kaufman, 1988; Van Coetsem, 1988; Thomason, 2001: Chap. 4.) Second, in dialect borrowing, where both lexicon and structure of the source and receiving languages overlap to a very great extent, structure is often transferred without morphemes. The same is true of interference between very closely related languages.

One example in the latter category is an innovative phonological rule in dialects of certain K'ichean languages of the Mayan family that are in intimate contact with Mayan languages of the Mamean branch of the family. This is a dissimilation rule that palatalizes velar stops when there is a uvular later in the word (Campbell, 1998: 74). A morphological example that also belongs in this category is found in the Serbo-Croatian dialect of Hvar, as described by Hraste (1935: 17–25). In the 1930s, elderly speakers of the dialect still used their inherited pattern of syncretism in the oblique plural noun cases of *o*-stem nouns, according to which the genitive/locative plural suffix *-ih* was opposed to a dative/instrumental plural suffix *-ima*. But under the influence of Standard Serbo-Croatian, younger Hvar speakers had replaced this pattern with the Standard one, in which the genitive plural suffix is unique to the genitive and opposed to a single dative/instrumental/locative plural suffix. But only the distribution of the suffixes changed; the original Hvar suffixes remained *-ih* and *-ima*, in partial contrast to the Standard Serbo-Croatian genitive plural *-a*: vs. *-ima*. In other words, only the syncretism rule has been borrowed.

A morphological example resulting from shift-induced interference led to the emergence of the

so-called 'second genitive,' a partitive case, in Russian. Although old interference from Uralic languages in Proto-Slavic is controversial, in part because of the paucity of Uralic loanwords (which, however, is actually characteristic of shift-induced interference; see Thomason and Kaufman, 1988: 238–251 for discussion of Slavic/Uralic contact), more recent shift-induced interference from shifting Uralic (probably Finnic) speakers to Russian is not. One generally agreed-on instance is the development, in the singular of *o*-stem nouns, of a partitive construction alongside the inherited genitive construction. The partitive, or second genitive, case suffix *-u* is native to Russian; it was originally the genitive singular suffix of a now-vanished noun class that was parallel to the *o*-stems. The genitive case suffix *-a*, which used to fulfill partitive as well as other 'genitive' functions in the *o*-stems (as did *-u* in the other noun class), is also native. The preservation of the *-u* suffix and its restructuring into a partitive suffix is due to imperfect learning of Russian by shifting Uralic speakers whose native language(s) had such a distinction. As a result, Modern Russian distinguishes phrases such as *čaška čaj-u* 'cup of tea' (literally 'cup tea-PARTITIVE') from phrases like *cena čaj-a* 'price of tea' (literally 'cup tea-GENITIVE').

Examples of this general type can easily be multiplied. Another typical set of examples comes from the Indic language Shina, which has acquired a sizable number of morphosyntactic features from shifting Burushaski speakers (the examples in this paragraph are all from Lorimer (1937), and other examples may also be found there). No transferred morphemes relevant to these constructions are found in Shina; the patterns must therefore have entered Shina as patterns, not via abstraction from lexical items. Among Lorimer's examples are plural verb agreement with an interrogative pronoun; a singulative suffix derived from the numeral for 'one' and ordered in a suffix string as in Burushaski; and a discourse feature, used in narratives, in which a sentence begins with the verb of the preceding sentence, in the infinitive form and with an oblique case suffix (dative in Burushaski and the accidentally homophonous locative in Shina).

All the evidence that rules can be transferred from one language to another leaves a vital question unanswered: by what process(es) is rule transfer implemented? Crucially, this question pertains to the innovation itself, not to the spread of an innovation through a speech community. A focus on the individual's innovation rather than the group's adoption of an innovation separates the analytic issues addressed here from issues typically studied in (socio) historical linguistic investigations, e.g., those of Labov (1994: 45) and Hopper and Traugott (1993: 38); both of these passages are cited in Hale, 2003). Of course both the innovation and the spread of a change must fit into a single overall picture of linguistic change; but the innovation seems a reasonable place to start, because all the proposed constraints on rule borrowing (and other kinds of contact-induced change) are aimed, ultimately, at the issue of (im)possible innovations, not of (im)possible spread.

A focus on the individual's innovation in accounting for linguistic change is preferred by many historical linguists, but it is especially prevalent among generativists. If, as generative historical linguists tend to believe (see, e.g., Hale, 2003; Lightfoot, 2003), children are the sole agents of language change, and if all change occurs during first-language acquisition as the result of a difference between "the grammar generating the primary linguistic data (PLD) used by an acquirer and the grammar ultimately constructed by that acquirer" (Hale, 2003: 345), then it is difficult to see how most kinds of contact-induced change – in particular shift-induced interference, which requires imperfect second-language learning – could occur at all. This is especially true given another assumption common among generativists, namely, that adults cannot change the grammar they internalized during first-language acquisition.

There is good evidence that children who are growing up bilingual create grammatical constructions that fall under the rubric of rule borrowing, at least from a retrospective viewpoint. One of the most striking examples in the literature is in Queen's research on a group of schoolchildren who grew up bilingual in Turkish (their parents' language) and German (the main language of the community) (Queen, 1996, 2001). These children received input from both languages for first-language acquisition, and that input included a Turkish clausal intonation pattern and a German clausal intonation pattern that performed the same syntactic function. Queen found that the children dealt with the competition between these patterns by incorporating both of them into both their languages and introducing a functional distinction between them – analogous to the preservation in English of the old past tense *hung* of the verb *hang* after the appearance of the analogically formed innovative past tense *hanged*, with a novel semantic distinction introduced between the two past tense forms (roughly, *hanged* for executing people by hanging, *hung* for hanging anything other than a person). Significantly, neither Turkish- nor German-speaking adults in the community noticed the innovation in either language, which suggests that the innovations were nonsalient. The process itself seems akin to rule borrowing, but with a difference: cases of rule borrowing, both the clear ones and the indeterminate ones,

involve one-way transfer of rules from one language to another, not a process through which competing structures are retained in both languages. And children's bilingual first-language acquisition *per se* is very unlikely to lead directly to anything that looks like shift-induced interference, because failure to learn target-language structure is characteristic of second-language acquisition, not of first-language acquisition.

In other words, adults, or at least people beyond the age of first-language acquisition, must play a role in rule borrowing. Some generativists have claimed that adults can only add a few minor rules or other features to their language (e.g., Chomsky and Halle, 1968: 251), and that the grammar internalized in early childhood does not change at all. Aside from Queen's results, many, most, or all of the innovations discussed in this article first arose in adults' speech. The status of innovations in adults' speech is a matter of vigorous debate, but this issue need not be settled here. Whatever the status of borrowed rules may be in an innovating adult's speech, they must comprise part of the adult's linguistic knowledge, because they are used systematically. They will therefore form part of the input to the next generation of language acquirers in the speech community, and so the innovation is integrated into the community's language. But the innovators are not the first-language acquirers but the adults who implement the borrowing. Rule borrowing proceeds, then, either as partial activation of one of a bilingual adult's languages while he or she is speaking the other language (see, e.g., Grosjean and Soares, 1986) or as a carryover from the first language of someone who is trying to learn, because he or she is shifting to, a target language. (This set of options is oversimplified, but space does not permit exploring more subtle distinctions here.) In all cases, of course, the innovation will not become a change in the language until and unless other speakers innovate in the same way and, eventually, learn the innovation from the original innovators. But the innovation itself, in this as in most cases of contact-induced language change, appears to originate in adult speech.

Finally, a bibliographical note. The literature on rule borrowing is not rich – or rather, many examples are discussed in the literature, but the topic of rule borrowing itself is not often addressed directly. The present article is based largely on Thomason (in press); other treatments of the topic are Campbell (1976), for phonology, and Harris and Campbell (1995: Chap. 6), for syntactic borrowing.

Rule Ordering and Derivation in Phonology

J Rubach, University of Iowa, Iowa City, IA, USA

© 2006 Elsevier Ltd. All rights reserved.

The goal of phonological theory is the discovery of generalizations. In classic generative phonology, generalizations are stated as rules, which are formalized in terms of distinctive features. Rules derive surface (phonetic) representations from underlying representations. This process, called derivation, will be illustrated by looking at a fragment of Polish phonology. The idea is to discover several different rules and to see how they interact with each other.

At the level of phonetic representation, Polish is known to have the so-called nasal diphthongs, which are sequences of a nasalized vowel followed by a nasal glide. For instance, the word *wąsy* 'moustache' is pronounced [vɔ̃w̃sɨ], where the macron over the vowel and the glide means [+nasal]. Nasal diphthongs occur only before fricatives. This distributional generalization must be somehow reflected in the grammar of Polish. A widely accepted analysis (see, for instance, Gussmann, 1980, and Rubach, 1984) is to treat nasal diphthongs as derivable from underlying oral vowels and the nasal consonant //n//. (Note: I use double slashes for underlying representations, single slashes for intermediate stages, and square brackets for phonetic representations.) In this analysis, *wąsy* comes from the underlying //vɔnsɨ//. The //n// is turned into [w̃] by Nasal Gliding.

(1) Nasal Gliding: n → w̃ before fricatives.

Note: this and the other rules below are stated schematically in an informal way in order to sidestep the problem of which of several existing distinctive feature theories should be used.

Nasalized vowels are also limited distributionally: they occur before the nasal glides [w̃] and [j̃]. (The latter will not be discussed here.) This generalization is captured by Vowel Nasalization.

(2) Vowel Nasalization: V → Ṽ before nasal glides.

The underlying //vɔnsɨ// is turned into the phonetic [vɔ̃w̃sɨ] by applying Nasal Gliding and Vowel Nasalization.

(3) //vɔnsɨ//
vɔw̃sɨ Nasal Gliding
vɔ̃w̃sɨ Vowel Nasalization
[vɔ̃w̃sɨ]

This derivation is completed by applying Stress Assignment, a rule of Polish that puts stress on the penultimate vowel of the word. The phonetic representation is thus [vɔ̃w̃sɨ], where the stressed vowel has been bolded.

Let us now analyze how the rules deriving [vɔ̃w̃sɨ] are related to each other. Notice that the stage in the derivation at which Stress Assignment applies is irrelevant: Stress Assignment could apply as the first or as the second or as the last rule in (3). Such ordering relations between rules are termed nonaffecting, i.e., the rules are in a **nonaffecting order**. The relation between Nasal Gliding and Vowel Nasalization is different. If the rules applied in the reverse order, the surface output would have been [vɔ̃w̃sɨ], with the vowel being oral rather than nasal, which is incorrect.

(4) //vɔnsɨ//
– Vowel Nasalization
vɔ̃w̃sɨ Nasal Gliding
*[vɔ̃w̃sɨ]

Vowel Nasalization cannot have an effect in (4) because the vowel is not followed by a nasal glide at the stage of the derivation at which Vowel Nasalization has been assumed to apply. Because only the result in (3) is correct, we have evidence for the fact that Nasal Gliding and Vowel Nasalization need to be ordered. The question is whether ordering can follow from some general principle or whether it must be stipulated for individual rules.

Notice that the ordering of Nasal Gliding before Vowel Nasalization can be assumed to be natural since otherwise Vowel Nasalization could never apply in any derivation because nasal glides are not

Rule Ordering and Derivation in Phonology

J Rubach, University of Iowa, Iowa City, IA, USA

© 2006 Elsevier Ltd. All rights reserved.

The goal of phonological theory is the discovery of generalizations. In classic generative phonology, generalizations are stated as rules, which are formalized in terms of distinctive features. Rules derive surface (phonetic) representations from underlying representations. This process, called derivation, will be illustrated by looking at a fragment of Polish phonology. The idea is to discover several different rules and to see how they interact with each other.

At the level of phonetic representation, Polish is known to have the so-called nasal diphthongs, which are sequences of a nasalized vowel followed by a nasal glide. For instance, the word *wąsy* 'moustache' is pronounced [vɔ̃w̃sɨ], where the macron over the vowel and the glide means [+nasal]. Nasal diphthongs occur only before fricatives. This distributional generalization must be somehow reflected in the grammar of Polish. A widely accepted analysis (see, for instance, Gussmann, 1980, and Rubach, 1984) is to treat nasal diphthongs as derivable from underlying oral vowels and the nasal consonant //n//. (Note: I use double slashes for underlying representations, single slashes for intermediate stages, and square brackets for phonetic representations.) In this analysis, *wąsy* comes from the underlying //vɔnsɨ//. The //n// is turned into [w̃] by Nasal Gliding.

(1) Nasal Gliding: n → w̃ before fricatives.

Note: this and the other rules below are stated schematically in an informal way in order to sidestep the problem of which of several existing distinctive feature theories should be used.

Nasalized vowels are also limited distributionally: they occur before the nasal glides [w̃] and [j̃]. (The latter will not be discussed here.) This generalization is captured by Vowel Nasalization.

(2) Vowel Nasalization: V → Ṽ before nasal glides.

The underlying //vɔnsɨ// is turned into the phonetic [vɔ̃w̃sɨ] by applying Nasal Gliding and Vowel Nasalization.

(3) //vɔnsɨ//
vɔw̃sɨ Nasal Gliding
vɔ̃w̃sɨ Vowel Nasalization
[vɔ̃w̃sɨ]

This derivation is completed by applying Stress Assignment, a rule of Polish that puts stress on the penultimate vowel of the word. The phonetic representation is thus [vɔ̃w̃sɨ], where the stressed vowel has been bolded.

Let us now analyze how the rules deriving [vɔ̃w̃sɨ] are related to each other. Notice that the stage in the derivation at which Stress Assignment applies is irrelevant: Stress Assignment could apply as the first or as the second or as the last rule in (3). Such ordering relations between rules are termed nonaffecting, i.e., the rules are in a **nonaffecting order**. The relation between Nasal Gliding and Vowel Nasalization is different. If the rules applied in the reverse order, the surface output would have been [vɔ̃w̃sɨ], with the vowel being oral rather than nasal, which is incorrect.

(4) //vɔnsɨ//
– Vowel Nasalization
vɔ̃w̃sɨ Nasal Gliding
*[vɔ̃w̃sɨ]

Vowel Nasalization cannot have an effect in (4) because the vowel is not followed by a nasal glide at the stage of the derivation at which Vowel Nasalization has been assumed to apply. Because only the result in (3) is correct, we have evidence for the fact that Nasal Gliding and Vowel Nasalization need to be ordered. The question is whether ordering can follow from some general principle or whether it must be stipulated for individual rules.

Notice that the ordering of Nasal Gliding before Vowel Nasalization can be assumed to be natural since otherwise Vowel Nasalization could never apply in any derivation because nasal glides are not

members of the underlying inventory of Polish, i.e., they all come from the application of Nasal Gliding. Consequently, the ordering of Vowel Nasalization before Nasal Gliding would be tantamount to saying that Vowel Nasalization does not exist as a rule of Polish. But Vowel Nasalization does exist in Polish, so the only possible ordering is the one that will permit Vowel Nasalization to apply, i.e., after Nasal Gliding. To put it differently, these rules order themselves automatically, a situation that is termed **intrinsic ordering**.

Not all the rules of the grammar order themselves intrinsically. Some rules require special stipulations that do not follow from any general principle (but see, for example, Kiparsky, 1971). Such stipulations are called **extrinsic ordering**. Extrinsic orders are of four basic types: feeding order, counterfeeding order, bleeding order, and counterbleeding order (Kiparsky, 1968, 1971). Each of these types is discussed separately below.

In Polish, the dental nasal //n// assimilates to the place of articulation of the following stop consonant, as shown in (5).

(5) sęp //sɛnp// → [sɛmp] 'vulture'
pręt //prɛnt// → [prɛnt] 'rod'
bąk //bɔnk// → [bɔŋk] 'gadfly'

The relevant rule is Nasal Assimilation.

(6) Nasal Assimilation: *n* assumes the place of articulation of the following stop consonant.

Furthermore, Polish has a pattern of alternations between [ɛ] and zero, as in *bez* 'lilac' NOM SG—*bz-y* NOM PL and *oset* 'thistle' NOM SG—*ost-y* NOM PL. The *e* that deletes is called a yer. An analysis of the behavior of yers is a matter of much controversy in the literature and will not be presented here (see, for example, Gussmann, 1980; Rubach, 1984, 1986). In a simplified way, Yer Deletion can be stated as the following rule.

(7) Yer Deletion:
ɛ → Ø before a single consonant followed by an inflectional vowel ending.

Consequently, //ɛ// deletes in the plural forms *bz-y* and *ost-y* but not in the singular forms *bez* and *oset* cited earlier.

With this background, we look at the assimilation facts in (8). The examples are nouns in the LOC SG form.

(8) bank-u 'bank': //bank-u// → [baŋk-u]; Nasal Assimilation applies;
pąk-u 'bud': //pɔnk-u// → [pɔŋk-u]; Nasal Assimilation applies;
BUT gank-u 'porch': [gank-u]; Nasal Assimilation does not apply.

The question is why Nasal Assimilation fails to apply to *gank-u*. The reason becomes clear when we look at the NOM SG forms of the words in (8): *bank* [baŋk], *pąk* [pɔŋk] and *ganek* [ganɛk]. Only the last word has [ɛ] between the nasal and the stop in the NOM SG. This *e* must be a yer at the underlying level because it deletes when the ending *-u* is added in the LOC SG: *gank-u*. The underlying representation of *gank-u* is therefore //ganɛk-u//. The yer blocks Nasal Assimilation, so the order of the rules must be Nasal Assimilation before Yer Deletion, as shown by the derivation in (9), which represents the facts of the Warsaw dialect of Polish.

(9) Warsaw Polish:
//bank-u// //pɔnk-u// //ganɛk-u//

baŋk-u	pɔŋk-u	–	Nasal Assimilation
–	–	gank-u	Yer Deletion
[baŋku]	[pɔŋku]	[ganku]	

The order in (9) must be stipulated, so it is extrinsic rather than intrinsic.

Interestingly, the nasal assimilation facts are different in the Cracow dialect of Polish. In this dialect, we witness assimilation not only in *bank-u* [baŋk-u] and *pąk-u* [pɔŋk-u] but also in *gank-u* [gaŋk-u]. The analysis is that Cracow Polish reverses the order of the rules in (9).

(10) Cracow Polish:
//bank-u// //pɔnk-u// //ganɛk-u//

–	–	gank-u	Yer Deletion
baŋk-u	pɔŋk-u	gaŋk-u	Nasal Assimilation
[baŋku]	[pɔŋku]	[gaŋku]	

The interaction between Yer Deletion and Nasal Assimilation in Cracow Polish is such that Yer Deletion creates the environment for the application of Nasal Assimilation to *gank-u*: after the deletion of the yer ɛ, the nasal stands next to the stop, so Nasal Assimilation can apply. We say that Yer Deletion and Nasal Assimilation apply in a **feeding order** in Cracow Polish, i.e., Yer Deletion feeds Nasal Assimilation.

The analysis of Warsaw Polish in (9) is different. The ordering of Nasal Assimilation before Yer Deletion makes the former rule inapplicable to *gank-u* //ganɛk-u//, which decreases the number of inputs to Nasal Assimilation. We say that Yer Deletion counterfeeds Nasal Assimilation in Warsaw Polish: the rules apply in a **counterfeeding order**.

To summarize, rules X ordered before Y are in a feeding order if X changes inputs in such a way that Y becomes applicable, as in (10). The opposite order is counterfeeding. If Y is ordered before X and attempts to apply but cannot do so because X has not applied yet, then X counterfeeds Y, as in (9).

A bleeding relation between rules is illustrated by the interaction of Fricative Devoicing and Voice Assimilation. Obstruent clusters in Polish must agree in voicing, i.e., they are either voiceless or voiced. This surface-true generalization is an effect of either of the following rules: Voice Assimilation, which applies regressively, or Fricative Devoicing, which applies progressively.

Voice Assimilation is a general rule that affects all obstruents and causes either voicing or devoicing. The decision of whether we have voicing or devoicing rests with the obstruent on the right, i.e., the obstruent that follows. Thus, the rule applies regressively, as shown in (11).

(11) a. Devoicing:
wesz [vɛʃ] 'louse' NOM SG – wsz-y [fʃ-ɨ] NOM PL, hence //vɛʃ-ɨ// → [fʃ-ɨ]

b. Voicing:
liczeb-n-y [litʃɛb-n-ɨ] 'numerous' – liczb-a [lidʒb-a] 'number'; the underlying representation of *liczb-a* is //litʃɛb-a// containing //tʃ//and the yer //ɛ//, both of which occur on the surface in the adjective *liczeb-n-y*, where the *-n* is the adjectivizing morpheme and the *–y* is the NOM SG ending of the adjective declension. The noun *liczb-a* undergoes Voice Assimilation: //litʃɛb-a// → [lidʒb-a]. (Consonants before *i* are soft, that is, palatalized, but I suppress this allophonic detail here and below.)

Voice Assimilation is stated informally as follows.

(12) Voice Assimilation: An obstruent assumes the feature [−voice] or [+voice] from the obstruent that follows.

Clusters of a voiceless obstruent followed by a voiced fricative behave differently from the way predicted by Voice Assimilation: the voiced fricative devoices under the influence of the preceding voiceless obstruent, i.e., the direction of assimilation is progressive rather than regressive. This observation is illustrated by words such as *bitw-a* [bitf-a] 'battle,' whose underlying representation is //bitɛv-a//. Both the yer and the voiced fricative //v// are motivated by the alternations in the adjective *bitew-n-y* [bitɛv-n-ɨ] 'warlike.' (Here, unlike in *bitw-a*, Yer Deletion is inapplicable, as the yer is separated from the following vowel suffix by two consonants.) In the noun *bitw-a* //bitɛv-a//, the two obstruents come together after the yer has been deleted: //bitɛv-a// → /bitv-a/. The /tv/ is devoiced to [tf] by Fricative Devoicing, a progressive assimilation rule.

(13) Fricative Devoicing: Fricatives become voiceless after a voiceless obstruent.

Notice that the intermediate derivational stage /bitv-a/ could potentially be an input to either Voice Assimilation or to Fricative Devoicing. In the former case, we would obtain a voiced cluster, which is incorrect: /bitv-a/ → *[bidv-a]. The attested output [bitf-a] is derived by applying Fricative Devoicing: /bitv-a/ → [bitf-a]. This result is delivered by the ordering of Fricative Devoicing before Voice Assimilation. The derivations of *bitw-a* as well as of *wsz-y* 'lice' and *liczb-a* 'number' cited in (11) are as follows.

(14)	//vɛʃ-ɨ//	//litʃɛb-a//	//bitɛv-a//	
	vʃ-ɨ	litʃb-a	bitv-a	Yer Deletion
	–	–	bitf-a	Fricative Devoicing
	fʃ-ɨ	lidʒb-a	–	Voice Assimilation
	[fʃ-ɨ]	[lidʒb-a]	[bitfa]	

Fricative Devoicing applies only to /bitv-a/ because this is the only word that meets the rule's environment: a voiced fricative is after a voiceless obstruent. (In /litʃb-a/, the obstruent after /tʃ/ is voiced but it is a stop /b/ and not a fricative, so Fricative Devoicing cannot apply.)

The relation between Fricative Devoicing and Voice Assimilation reveals a new type of extrinsic ordering: a **bleeding order**, which is defined as an ordering relation under which the application of one rule destroys the environment for the application of another rule. (The ordering of Yer Deletion before Fricative Devoicing is feeding because the deletion of the yer provides a context for the application of Fricative Devoicing.) The application of Fricative Devoicing in (14) removes /bitv-a/ from the list of inputs to Voice Assimilation (more accurately: to its part that is responsible for voicing). After the /tv/ has been changed into [tf], the voicing, /tv/ → [dv], is no longer possible: Fricative Devoicing and Voice Assimilation are in a bleeding order, i.e., Fricative Devoicing bleeds Voice Assimilation. (Actually, if Voice Assimilation applied before Fricative Devoicing turning /tv/ into [dv], Fricative Devoicing also would have been bled, so in fact Fricative Devoicing and Voice Assimilation stand in a mutually bleeding relation.)

Finally, rules may stand in a **counterbleeding order**, which is the reverse of the bleeding order. Rules X and Y are in a counterbleeding order if rule X applying

before Y fails to destroy the context for the application of rule Y. That is, Y would have bled X if the order were Y before X. This rather complex relation is illustrated by the interaction between Yer Deletion and Velar Palatalization.

Velar consonants //k g x// change into postalveolars [tʃ dʒ ʃ] before front vowels, a process that is known as Velar Palatalization.

(15) Velar Palatalization k g x → tʃ dʒ ʃ before front vowels.

The operation of this rule is illustrated in (16), where we look at the alternations triggered by the diminutive suffix *–ek*.

(16) kro*k* 'step' – krocz-ek [krɔtʃ-ɛk] NOM SG – krocz-k-u [krɔtʃ-k-u] LOC SG
mózg 'brain' – móżdż-ek [muʒdʒ-ɛk] NOM SG – móżdż-k-u [muʃtʃ-k-u] LOC SG
gro*ch* (*ch* stands for [x]) 'pea' – grosz-ek [grɔʃ-ɛk] NOM SG – grosz-k-u [grɔʃ-k-u] LOC SG

A comparison of the diminutive forms in the NOM SG and LOC SG shows that the *e* of the suffix *–ek* is a yer because it deletes when a vowel ending is added to the stem, as in the LOC SG. The point of interest is that Velar Palatalization takes effect not only in the NOM SG, where the front vowel *e*, a trigger of the rule, is present overtly on the surface but also in the LOC SG, where //ɛ// has been deleted by Yer Deletion. Clearly, the ordering of Velar Palatalization and Yer Deletion must be such that Velar Palatalization applies at the stage when //ɛ// is still present, i.e., before Yer Deletion can have an effect. In (17), we look at the derivation of the LOC SG form *grosz-k-u* 'pea,' whose underlying representation is //grɔx-ɛk-u//, with //x// being motivated by its occurrence in the nondiminutive form *groch* [grɔx].

(17) //grɔx-ɛk-u//
grɔʃ-ɛk-u Velar Palatalization
grɔʃ-k-u Yer Deletion
[grɔʃku]

Velar Palatalization and Yer Deletion apply in a **counterbleeding order**, which is the opposite of the bleeding order. Notice that if Yer Deletion were ordered before Velar Palatalization, then Velar Palatalization would have been bled (i.e., blocked) in its application to *grosz-k-u*, as shown in (18).

(18) //grɔx-ɛk-u//
grɔx-k-u Yer Deletion
– Velar Palatalization
*[grɔxku]

To summarize, a bleeding order is one in which the application of one rule destroys the environment for the application of another rule. We saw this in (14), where Fricative Devoicing made the application of Voice Assimilation impossible. The opposite relation where the order could have been bleeding but actually is not is called counterbleeding. This was illustrated in (17): the ordering of Yer Deletion after Velar Palatalization made the latter rule applicable.

Derivations can be long and complex. Such is the case for the LOC SG form *drąż-k-u* [drɔ̃w̃ʃ-k-u] 'pole' (diminutive). The underlying representation here is //drɔng-ɛk-u// and it is motivated as follows.

As noted earlier, the diminutive suffix has a yer because it shows an *e* – zero alternation seen in (16). Actually, this alternation is found also in the example under discussion because the NOM SG of *drąż-k-u* is *drąż-ek* [drɔ̃w̃ʒ-ɛk]. A comparison of [drɔ̃w̃ʃ-k-u] LOC SG and [drɔ̃w̃ʒ-ɛk] NOM SG shows that the root-final consonant must be voiced at the underlying level: we see the voiced [ʒ] in [drɔ̃w̃ʒ-ɛk]. The voiceless [ʃ] in the LOC SG [drɔ̃w̃ʃ-k-u] must therefore be due to Voice Assimilation: the devoicing of /ʒ/ to [ʃ] before the voiceless obstruent [k].

However, *ʒ* is not the underlying segment in the root morpheme, because we see [g] in the non-diminutive LOC SG form *drąg-u* [drɔŋg-u]. That is, the [ʒ] of *drąż-ek* [drɔ̃w̃ʒ-ɛk] DIMIN NOM SG alternates with the [g] of *drąg-u* [drɔŋg-u] LOC SG. Polish has a rule that derives [ʒ] but this rule, known as Spirantization, applies to /dʒ/ and not to /g/.

(19) Spirantization: dʒ → ʒ after sonorants.

The rule is restricted to the context of sonorants, because it does not apply if the preceding consonant is an obstruent. Consequently, there is not spirantization of *dʒ* to *ʒ* in *mózg* 'brain' – *móżdż-ek* [muʒdʒ-ɛk]. (The [ʒ] in [muʒdʒ-ɛk] is of a different origin: it is an effect of assimilation of /z/ to [ʒ] before [dʒ].)

Returning to *drąż-k-u*, we note that the derivation of /ʒ/ from //g// is possible if //g// is turned into /dʒ/ because then Spirantization becomes applicable. What we need is to find a way of changing the underlying //g// into /dʒ/. The solution is simple: the yer of the diminutive suffix //ɛk// triggers Velar Palatalization, hence //g// → /dʒ/.

Finally, the glide [w̃] is derived from //n// by Nasal Gliding, rule (1) discussed earlier. The derivation is completed by applying Vowel Nasalization (2) that nasalizes vowels before nasal glides.

In sum, the derivation for the LOC SG form //drɔng-ɛk-u// → [drɔ̃w̃ʃku] is as follows. (Stress Assignment is ignored.)

(20) //drɔng-ɛk-u//
drɔndʒ-ɛk-u Velar Palatalization
drɔnʒ-ɛk-u Spirantization

drɔnʒ-k-u	Yer Deletion
drɔw̃ʒ-k-u	Nasal Gliding
drɔ̃w̃ʒ-k-u	Vowel Nasalization
drɔ̃w̃ʃ-k-u	Voice Assimilation
[drɔ̃w̃ʃku]	

This derivation presents an array of various ordering relations between rules.

i. Some rules are **nonaffecting**, i.e., they are not related, so their ordering is irrelevant. This is true for Spirantization and Yer Deletion as well as for Voice Assimilation and Nasal Gliding or Vowel Nasalization.
ii. The ordering of Vowel Nasalization after Nasal Gliding is **intrinsic**. That is, if the order were reversed, then Vowel Nasalization would never have a chance to apply in Polish because all nasal glides are derived by Nasal Gliding and none exist in the underlying representation of Polish morphemes. Similarly, if Polish has no underlying //dʒ// (this is not fully accurate but let us ignore it here), the ?show =x(100)?> ordering of Spirantization after Velar Palatalization is intrinsic because this is the only imaginable order that would give Spirantization a chance to apply and hence document its presence in the grammar of Polish.
iii. Velar Palatalization and Yer Deletion stand in a **counterbleeding** relation: if the latter applied first, Velar Palatalization would have been bled since its trigger, the front vowel, would have been deleted. Counterbleeding is also true for Voice Assimilation and Spirantization: if Voice Assimilation were to apply before Spirantization, then Spirantization would have been bled because the intermediate /dʒ/would have been turned into /ʧ/, and Spirantization works on /dʒ/ and not on /tʃ/.
iv. The relation between Yer Deletion and Voice Assimilation is **feeding** since the deletion of the /ɛ/ brings together a voiced obstruent (here /ʒ/) and a voiceless obstruent (here /k/), which makes Voice Assimilation applicable. Similarly, Spirantization feeds Nasal Gliding because the latter applies before fricatives, so it becomes applicable only after /dʒ/ has been turned into /ʒ/.

Rules and their application in derivation can be evaluated from the perspective of **transparency** and **opacity**, the concepts introduced by Kiparsky (1971, 1973). Judgments regarding transparency and opacity are formed on the basis surface phonetic facts. A rule is transparent if its application can be understood by inspecting surface representations alone, without recourse to intermediate derivational stages. Opacity is the reverse of transparency. If no rationale for the application of a certain rule can be found in the surface structure, then the rule is opaque. The fragment of Polish phonology presented in the preceding paragraphs bears witness to both transparent and opaque rules.

Vowel Nasalization stated in (2) is a classic example of a transparent rule. Recall that vowels are nasalized before nasal glides and that Vowel Nasalization is the only source of nasalized vowels. That is, nasalized vowels do not exist in the underlying representation and they do not come from any other rule. The situation is simple: if we see a nasalized vowel, then it is always followed by a nasal glide, and there are no exceptions to this generalization. Thus, we can always see in the surface representation the rationale for the occurrence of nasalized vowels. To put it differently, the trigger of the rule, a nasal glide, and the effect of the rule, a nasalized vowel, are always visible in the surface representation. Since Vowel Nasalization is ordered intrinsically after Nasal Gliding (1), the generalization is that intrinsic order leads to transparency. Transparency is also the property of the rules that stand in two other ordering relations: feeding and bleeding.

The feeding order between Nasal Assimilation and Yer Deletion in Cracow Polish makes Nasal Assimilation a fully transparent rule. This is documented by the fact that all surface occurrences of [ŋ] before stops are due to Nasal Assimilation. We see [ŋ] not only in *bank* [baŋk] 'bank' but also in *gank-u* [gaŋk-u] 'porch' LOC SG; recall the derivation in (10).

The bleeding order between Fricative Devoicing and Voice Assimilation makes Fricative Devoicing transparent. First, there are no surface representations that would contradict the operation of Fricative Devoicing because clusters of obstruents are always uniform in their value for [±voice]. Second, the trigger of devoicing, a voiceless obstruent preceding the fricative, is always present in the surface representation.

Whereas feeding and bleeding orders lead to transparency, counterfeeding and counterbleeding orders cause opacity. A rule is opaque if we find derivations in which the application of this rule cannot be explained by looking at surface representations. The counterfeeding relation between Nasal Assimilation and Yer Deletion in Warsaw Polish is an example in point. The occurrence of [nk] rather than the expected [ŋk] in *gank-u* [gank-u] 'porch' LOC SG is not understandable from the point of view of surface representations. There is no answer to the question of why Nasal Assimilation has not applied to *gank-u*, given that the task of the rule is to assimilate /n/ to the following stop and [n] is followed by [k] in this example. The reason for the failure of Nasal Assimilation to apply to *gank-u* is hidden at an intermediate derivational stage. Recall Nasal Assimilation applies in

Warsaw Polish at the stage at which the underlying yer of //ganɛk-u// has not been deleted yet by Yer Deletion. Consequently, the nasal and the stop are not adjacent when Nasal Assimilation applies: Yer Deletion counterfeeds Nasal Assimilation. Later the yer deletes, yielding the unassimilated cluster [nk]. The absence of assimilation makes Nasal Assimilation opaque.

The counterbleeding order between Velar Palatalization and Yer Deletion in (17) shows that Velar Palatalization is opaque. The reason is that the change of the underlying //x// into [ʃ] in *grosz-k-u* 'pea' DIMIN LOC SG, //grɔx-ɛk-u// → [grɔʃ-k-u], makes no sense from the point of view of the surface representation. Since the trigger of Velar Palatalization, the yer *e*, is not present on the surface, we find no answer to the question of why Velar Palatalization has applied here.

McCarthy (1999) clarifies the concepts of transparency and opacity by evaluating phonological generalizations in terms of whether they are **surface-true** and **surface-apparent**. A rule is surface-true it is not violated in any regular way in surface representations. For example, Vowel Nasalization is surface-true because there are no instances of oral vowels before nasal glides in Polish. That is, Vowel Nasalization applies to vowels before nasal glides in an entirely exceptionless manner. The rule is also surface-apparent because its trigger, a nasal glide, is always present in the surface representation. More generally, a rule is surface-apparent if the reason for its application can be discovered by inspecting surface representations. Transparent rules are both surface-true and surface-apparent. In contrast, opaque rules fail on these criteria.

Nasal Assimilation in Warsaw Polish is not surface-true because it regularly fails to apply to words such as *gank-u* 'porch' LOC SG. The reason for this failure – the occurrence of a yer – is not visible in the surface representation because the yer has been deleted. That is, judging from the point of view of surface representations, Nasal Assimilation has a regular class of exceptions. The generalization is that not-surface-true rules are opaque.

Velar Palatalization is not surface-apparent. The evidence comes from words such as *grosz-k-u* 'pea' DIMIN LOC SG. Notice that the situation here is different from that found in *gank-u*. The word *grosz-k-u* [grɔʃ-k-u] is not a surface exception to Velar Palatalization because it does not have a velar consonant before a front vowel. That is, its surface representation is not *[grɔx-ɛk-u]. Rather, the problem is that we see no reason in the surface representation for why Velar Palatalization has applied here changing the underlying //x// into the surface [ʃ]: there is no front vowel in [grɔʃ-k-u] that could have triggered Velar Palatalization. A rule is not-surface apparent if its trigger is not visible in the surface representation. Such a rule is opaque. To conclude, opacity is the property of rules that are either not-surface-true or not-surface-apparent.

Finally, let us look at the relation between the domain of rules and extrinsic ordering. The point is that some (but not all) extrinsic orders can be predicted from the domain in which rules apply. This idea is best expressed in the model of Lexical Phonology, which draws a distinction between lexical and postlexical rules (Kiparsky, 1982; Booij and Rubach, 1987).

Lexical rules apply in the domain not larger than words because words and not phrases are derived in the lexicon. Postlexical rules are not limited in this way. They apply after the syntactic component of the grammar has put words together to form phrases and sentences, so postlexical rules use phrases and sentences as their domains. To put it differently, postlexical rules apply not only inside words but also across word boundaries. The distinction between lexical and postlexical rules is illustrated by the operation of Fricative Devoicing (13) and Voice Assimilation (12).

Recall that Fricative Devoicing must apply before Voice Assimilation (see (14)). This fact coincides with the observation that all instances in which Fricative Devoicing applies are strings that are wholly contained within the word. Consequently, Fricative Devoicing is a lexical rule. In contrast, Voice Assimilation cannot be regarded as lexical because we see it operating in phrase phonology.

(21) brat 'brother' NOM SG – brat-[brat-a] GEN SG, hence //brat//
BUT brat Barbabry [brad barbarɨ] 'Barbara's brother': /t#b/ → [d#b]
kod 'code' NOM SG – kod-u [kɔd-u] GEN SG, hence //kɔd//
BUT kod pocztowy [kɔt pɔʧtɔvɨ] 'postal code': /d#p/ → [t#p]

We conclude that Voice Assimilation is a postlexical rule.

The ordering of Fricative Devoicing before Voice Assimilation is now predicted correctly by the model of Lexical Phonology, whose tenet is that the lexical component of phonology (and hence the rules that constitute it) precedes the postlexical component (and hence the rules that constitute it).

The analysis of Fricative Devoicing and Voice Assimilation in terms of the lexical-postlexical distinction is corroborated by phrases that contain a

word-final voiceless obstruent followed by a word-initial voiced fricative, for instance, *brat wasz* //brat vaʃ// → [brad vaʃ] 'your brother.' According to Lexical Phonology, the phrase *brat wasz* does not exist in the lexical component in which lexical phonological rules apply. Rather, what we have is two separate words: *brat* and *wasz*. These words are processed separately by lexical rules. The consequence of this analysis is that the final /t/ of *brat* and the initial /v/ of *wasz* do not form the cluster /tv/ in the lexical component. In contrast, the /tv/ of *bitw-a* 'battle' is visible to lexical rules because the cluster is contained wholly within one word (recall the derivation in (14)). Fricative Devoicing, a lexical rule, takes effect, yielding [tf]. In the postlexical component, inputs are the structures derived by the syntax, hence phrases and sentences. It is there that *brat wasz* occurs as a phrase for the first time. (Let us assume that *bitwa* does not enter into any larger syntactic structure, hence it is a phrase itself.) Voice Assimilation, a postlexical rule, applies and voices the final /t/ of *brat* to [d], the correct result.

(22) Lexical component:

//bitɛv-a//	//brat//	//vaʃ//	
bitv-a	–	–	Yer Deletion
bitf-a	–	–	Fricative Devoicing

Postlexical component:

/bitfa/	/brat	vaʃ/	
–	brad	vaʃ	Voice Asssimilation
[bitfa]	[brad	vaʃ]	

To summarize, the word-internal /tv/ in *bitwa* and the phrasal /t v/ in *brat wasz* follow contradictory strategies in achieving the goal of making the cluster uniform with regard to the feature [±voice]: we see devoicing word-internally, /tv/ → [tf], and voicing in phrasal phonology, /t v/ → [d v]. These contradictions are reconciled by Lexical Phonology because, for independent reasons, Fricative Devoicing is a lexical rule, whereas Voice Assimilation is a postlexical rule. Because by definition lexical rules must precede postlexical rules, the extrinsic ordering between Fricative Devoicing and Voice Assimilation does not have to be stipulated any longer.

The final question is whether the concepts of ordering and derivation exist in the most recent version of generative phonology called Optimality Theory (Prince and Smolensky, 1993; McCarthy and Prince, 1995). The answer is that they exist, but the notion of derivation is highly controversial. Ordering appears in Optimality Theory as ranking, but it is the ranking of universal constraints and not the ordering of language-specific rules. Standard Optimality Theory rejects derivation and claims that phonological processing is carried out in a fully parallel (simultaneous) fashion, but there are researchers who claim that the rejection of derivation is an error (see, for example, Kiparsky, 2000; Rubach, 2000a, 2000b, 2003). The view of these researchers is that Optimality Theory should build on Lexical Phonology and admit three derivational levels: the stem level, the word level, and the postlexical level. Phonological processing within a level is fully parallel, as in standard Optimality Theory. However, the output of the stem level is the input to the word level, and the output of the word level is the input to the postlexical level, so we have derivational steps.

Rules and Principles

H van de Koot, University College London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The notions 'rule' and 'principle' lie at the heart of the generative approach to linguistics. A grammar in this tradition is not prescriptive but rather is a finite, mentally represented system of rules that specifies a native speaker's knowledge about the mapping between linguistic expressions and their meaning. The rules that make up this system fall in two types.

The first define the set of well-formed phonological, morphological, syntactic, or semantic structures for the language. It is often assumed that each of these subdomains has its own dedicated generative rule system, although there is no universal agreement on the matter.

The second type of rule maps between linguistic objects that are constructed by different generative rule systems. For example, if it is assumed that syntactic and phonological structures are generated by dedicated rule systems, then there must be mapping rules that determine which phonological structures may be associated with which syntactic structures.

Let us consider generative rule systems first. Proposing a linguistic rule is not a matter of stating an inductive generalization (that is, a generalization based on the observation of repeated 'patterns' in the data). The formulation of a rule invariably depends on previous hypotheses about the domain under investigation, namely concerning the inventory of primitive objects that rules can be defined over. To give an example from syntax, rules for sentence structure rely on the hypothesis that words are specified for syntactic category (a label taken from a small set such as {V,N,A,P}). Once that much has been assumed, it becomes possible to state a rule like (1), which says that a V (such as *reads*) and an N (such as *books*) form a verbal category called a VP (verb phrase).

Figure 1 A simple verb phrase.

(1) VP → V N

Traditionally, a linguistic rule maps one object to another. A typical example is the rewrite rule described earlier, which maps the category VP to a string consisting of two categories, namely V and N. However, such a rule can also be interpreted as a well-formedness constraint. Thus, (1) can be read as a principle licensing the partial tree structure (**Figure 1**), in which a VP has a V and an N as its daughters. As a result, in modern linguistics the words *rule* and *principle* (or *constraint*) are often used synonymously.

The second type of rule identified earlier relates linguistic objects of different types. Such mapping rules allow for various kinds of mismatches between the structures they relate. To see this, consider an example like *John expects Mary to win*, in which the syntactic phrasing groups *Mary* together with *to win* (as in [2]), while the prosodic structure groups *Mary* together with *expects*, so that *Mary* precedes a prosodic boundary (as in [3]).

(2) [[John] [expects [[Mary] [to [win]]]]]

(3) [John]φ [expects Mary]φ [to win]φ

This mismatch falls into place if the mapping rules that relate syntactic and prosodic structures determine that right edges of prosodic phrases coincide with right edges of syntactic phrases.

Rules and Rule-Following

A Miller, Macquarie University, Sydney, NSW, Australia

© 2006 Elsevier Ltd. All rights reserved.

Why are the notions of rules and rule-following of significance to the philosophy of language and linguistics? Inspired by the discussions of rule-following in Wittgenstein's *Philosophical investigations* (sections 138–242) and *Remarks on the foundations of mathematics* (section VI), Saul Kripke and Crispin Wright independently developed arguments that challenged our intuitive conception of *meaning* as both *factual* and *objective* (see Wright [1980], Chapters 2 and 12, and Kripke [1982]). In this article, we will focus on the rule-following issue as presented by Kripke.

Rule-Following and Meaning

Suppose that Jones intends to follow the rule 'Add 2' in continuing the series: 2, 4, 6, 8, 10, ... Jones can continue the series in ways that *accord* or *fail to accord* with the requirements of the rule. For example, the continuation 12, 14, 16, . . . would accord with the rule (as standardly understood), whereas the continuation 12, 13, 14, . . . would fail to accord with the rule (as standardly understood). In other words, the former continuation would be *correct* by the lights of the rule, whereas the latter would be *incorrect* by the lights of the rule: the rule provides a *normative standard* against which particular continuations can be assessed as correct or incorrect. Intending to follow a rule is analogous in certain respects to meaning something by a linguistic expression. The meaning of a linguistic expression provides a normative standard against which the uses of that expression can be assessed as correct (or incorrect), as according with that meaning (or failing to accord with that meaning). Thus, for example, given the usual meanings of the numerals and signs involved, and given the arithmetical fact that the sum of 68 and 57 is 125, the answer '125' to the query '68 + 57 = ?' will be correct by the lights of those meanings, whereas the answer '5' will be incorrect by the lights of those meanings.

Suppose that Jones has laboriously written out the series 2, 4, 6, 8, . . . , 996, 998. Is there a fact of the matter as to what rule he's been following in writing out this sequence? Ordinarily, we'd be inclined to say that there is a fact of the matter, and, that, in all likelihood, he's been following the rule 'Add 2' (and not, say, the rule 'add 3,' or not following any rule at all but simply writing down numerals at random). According to Kripke's Wittgenstein (hereafter 'KW'), this is an illusion: there is no fact of the matter as to what rule Jones has been following, and indeed no fact of the matter as to whether Jones has been following any rule at all. In similar fashion, we can ask whether there is a fact of the matter as to what meaning Jones associates with the '+' sign. Assuming that Jones's uses of the '+' sign have been roughly similar to our own, we'd be inclined ordinarily to say that there is a fact of the matter, and, that in all likelihood, he understands '+' to mean the *addition* function (and not, say, the multiplication function or no function whatsoever). As in the case of rules, KW claims that this is an illusion: there is no fact of the matter as to what Jones means by '+,' and indeed no fact of the matter as to whether he means anything at all by '+.'

Constitutive and Epistemological Skepticism

Before turning to KW's argument, we need to note a distinction between two types of skepticism. An *epistemological skeptic* about a particular area claims that we are not entitled to the knowledge claims that we typically make within it. Thus, for example, an epistemological skeptic about the external world (such as the skeptic who is Descartes's protagonist in his *Meditations*) would argue that I am not entitled to claim that I know that I am currently awake and sitting at a computer writing a philosophy essay. The epistemological skeptic doesn't question whether there is a fact of the matter as to whether I'm currently awake: he's happy to concede that there is a fact of the matter (either I'm awake, etc., or I'm not), and questions only whether I'm entitled to say that I know which of the two relevant possibilities is actually the case. *KW's skepticism about rule-following and meaning is not only epistemological skepticism*. KW argues, not only that we don't know whether we mean addition by '+,' or intend to follow the rule 'Add 2,' but also that there may not be anything *to* know. That is, not merely are we ignorant about what '+' means; there is no fact of the matter as to what it means – there is nothing for meaning facts to consist in or to be constituted out of. KW is thus a *constitutive skeptic* about rule-following and meaning. But as we'll see, KW takes an epistemological route to his constitutive skepticism.

KW's Skeptical Argument

Suppose that, in the examples above, Jones has never previously gone beyond 996 in his apparent attempts

to continue the arithmetical series generated by the rule 'Add 2,' and has never performed arithmetical calculations with numbers greater than 57 (the fact that Jones is a finite creature ensures that we can always set up this sort of scenario simply by choosing numbers that are large enough). If there were a fact of the matter as to what rule Jones is trying to follow, or a fact of the matter as to what meaning he associates with the '+' sign, there would be a fact of the matter as to how he ought to continue the number series (if he is to accord with the relevant rule), and a fact of the matter as to how he ought to answer the query '68 + 57 = ?' (if his practice is to accord with the relevant meaning). KW argues that there is no fact of the matter as to how he ought to continue the number series, and no fact of the matter as to how he ought to answer the query '68 + 57 = ?.' Who is to say that Jones does not, in the case of the number series, intend to follow the rule 'Zadd 2,' in which the result of zadding 2 to a number is the same as the result of adding 2 to a number for numbers less than 1,000 and the same as the result of adding 4 to a number for numbers greater than or equal to 1,000? If Jones intended to follow this non-standard rule in continuing the series, he ought to continue the series 998, 1000, 1004, 1008, ... and not as we'd expect, namely 998, 1000, 1002, 1004, 1006 ... and so on. Likewise, who is to say that Jones does not, in the case of the arithmetical calculation, understand '+' to mean, not the addition function but, rather, the *quaddition* function, in which the result of *quadding* two numbers x and y is the same as adding them when both x and y are less than 57 but, rather, 5, when either x or y is greater than or equal to 57? If Jones meant the quaddition function by the '+' sign, he ought to answer '5' to the query '68 + 57 = ?,' and not, as we'd expect, '125.'

KW's argument proceeds by allowing us *unlimited and omniscient access* to two broad categories of fact, and invites us to find the fact that constitutes Jones's intending to follow the 'Add 2' rule as opposed to the 'Zadd 2' rule, or Jones's meaning addition as opposed to quaddition by '+': facts about Jones's previous behavior and behavioral dispositions and facts about Jones's mental history and mental states. The assumption is that if facts about rule-following and meaning are to be found anywhere, they will be found within these two kinds of fact. So, if unlimited and omniscient access to these two classes of fact fails to turn up a fact that constitutes Jones's intending to follow one rule rather than another, or meaning one thing rather than another, it will follow that there is simply no such fact to be found. This is why we said above that KW's argument for constitutive skepticism proceeds via an epistemological route: KW argues that even given unlimited and omniscient access to facts about Jones's behavior and behavioral dispositions and facts about Jones's mental life, we still couldn't claim to know, or justify, a particular hypothesis about how Jones ought to continue the arithmetical series or answer the arithmetical query.

Facts about Jones's previous behavior won't do the trick, as all of that behavior is consistent with Jones's intending to follow the 'Zadd 2' rule or meaning the quaddition function by the '+' sign: *ex hypothesi*, he had never previously dealt with cases in which the numbers were large enough for 'Add 2' and 'Zadd 2,' or meaning addition and quaddition, to demand different responses (Kripke, 1982: 7–15). Facts about how Jones is disposed to continue the series, or answer arithmetical queries, won't turn the trick either. Even if it was true that *if* Jones had reached 1000, he *would* have continued 1004, 1008, and so on, or true that *if* he'd been asked '68 + 57 = ?' he *would* have answered '125' and not '5,' neither of these facts could plausibly be said to constitute his intending to follow one rule rather than another, or mean one function rather than another. Facts about the rule he intended to follow, or the meaning he attached, are *normative* facts, facts about how he *ought* to continue the number series or answer the arithmetical query. But the dispositional facts canvassed tell us at most what he *would* do in certain situations, as opposed to telling us what he *ought* to do in those situations (Kripke, 1982: 22–38). KW also rules out the following as facts constitutive of rule-following and meaning: *general thoughts* or *instructions* (1982: 15–17); relative *simplicity* of hypotheses about rule-following and meaning (1982: 38–40); *qualitative, introspectible, irreducibly mental states* (such as mental images) (1982: 41–51); *sui generis and irreducible mental states* (1982: 51–53); relations to *objective, Fregean senses* (1982: 53–54). Thus, according to KW there are no facts about rule-following and meaning, and these notions vanish 'into thin air'(1982: 22).

KW's Skeptical Solution

KW describes this result as a 'sceptical paradox,' and attempts to avoid the 'insane and intolerable' (1982: 60) conclusion that 'all language is meaningless' (1982: 71) via a 'sceptical solution.' The main idea of the skeptical solution is that judgments about rule-following and ascriptions of meaning can be viewed as possessing a *non-fact-stating role*, so that the practices of ours involving the notions of rule-following and meaning avoid the worries associated with the skeptical paradox. If the function of judgments about meaning is not to describe facts, the discovery that

there are no facts about meaning no longer threatens our practice of making such judgments. It emerges as a consequence of the detail of the skeptical solution that the notions of rule-following and meaning only have application relative to *communities* of rule-followers or speakers, not absolutely. In particular, it follows that 'solitary' language is impossible. (This is KW's take on Wittgenstein's famous 'private language argument.')

Significance of the Issue

Unless it is blocked, the skeptical paradox threatens to undermine the idea that we can give a *cognitive-psychological* explanation of, for example, semantic creativity: the capacity speakers' have to understand novel utterances. One way of essaying such an explanation would be in terms of speakers' knowledge of the meanings of the familiar constituents of the novel utterance and their proceeding from this to knowledge of the utterance's meaning in a way that mirrors the compositional route to the meaning of the utterance from the meanings of its constituents and their mode of syntactic combination. Clearly, if there are no facts about meaning there will be no facts about the meanings of novel utterances or their constituents, so that the whole project of cognitive-psychological explanation of semantic creativity will be undermined. That would be a consequence of the skeptical paradox about meaning. But the skeptical paradox about rule-following in general would have even more destructive consequences: one way of attempting to explain the capacity speakers have to distinguish grammatical from ungrammatical strings would proceed in terms of their implicit grasp of grammatical rules governing the language in question. Clearly, if there are no facts of the matter as to whether these rules classify a given novel string as grammatical or not, this whole project, too, will be thrown in jeopardy. For a particularly clear exploration of these issues, see Wright (1989). See also Baker and Hacker (1984).

Responses to the Skeptical Paradox and Skeptical Solution

For defenses of dispositionalist, or otherwise naturalistic, solutions to KW's skeptical paradox, see Forbes (1984), Fodor (1990), Millikan (1990), and Horwich (1998). For further discussion of dispositionalism, see Boghossian (1989: Section V), McManus (2000), and Miller (2003). For non-reductionist responses (according to which facts about meaning are not reducible to facts about non-semantically and non-intentionally characterized behavior or states), see McDowell (1984), McGinn (1984), Wright (1989), Boghossian (1989: Section VI), and Pettit (1990). Wright takes the rule-following arguments to threaten, not the factuality of meaning but, rather, the *objectivity* of meaning: see the Introduction to Wright (1993). For discussion of the skeptical solution and the argument against solitary language, see Blackburn (1984), Wright (1984), and Boghossian (1989: Sections II–IV). KW's skeptical solution was characterized above as a version of non-factualism about ascriptions of meaning, but this interpretation has been challenged by a number of philosophers: see, e.g., Wilson (1994) and Kusch (in press). For a searching examination of the normativity of meaning, see Hattiangadi (in press). For a reaction to KW from the perspective of a linguist, see Chomsky (1986). For an introductory survey and overview, see Miller (1998: Chaps. 5 and 6).

Runes

K A Lowe, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Runes are characters of the runic alphabet, a writing system employed by all Germanic peoples. Different runic scripts are used for different languages. Sweden has the largest number of runic inscriptions (over 3000), followed by Norway and Denmark. Iceland has surprisingly few, given the frequency of references to runes in its literature. Significant numbers of runic inscriptions also survive from Greenland, Germany/Austria, the Isle of Man, Orkney, and England.

The earliest runic inscriptions date from the late 2nd century A.D. Runes continued in use in Scandinavia until well into the medieval period, elsewhere not long after the 11th century. The origins of the runic alphabet, or *futhark* (named after the value of its first six letters, with *th* represented by ᚦ) are unclear. Three main theories still attract support: that the *futhark* was developed ultimately from the Greek, the Northern Italic, or the Roman alphabets.

Runes provide us with much of our earliest evidence concerning the languages of the Germanic peoples, and valuable information about their social history and societal structure. Runes and runic inscriptions are preserved on materials such as stone, wood, metal, and bone. They also appear in manuscripts. Runes were originally designed for inscriptional use, primarily for cutting on wood; hence, the shape of early runes, which avoid curved and horizontal lines.

Transliteration and Terminology

Bold letters are generally used for the transliteration of Continental and Scandinavian inscriptions. Practice varies with Anglo-Saxon inscriptions, but the system devised by Dickins (1932) and adapted by Page (1984; reprinted 1995 with postscript), using spaced letters within inverted commas, has much to commend it.

Runic inscriptions may occasionally be written right-to-left ('retrograde') or 'boustrephedon' (with lines written in alternating directions). Normally there is no word separation, and geminates are simplified.

Occasionally rune cutters ligatured two runes together, perhaps on account of space considerations. The result is a 'bind rune' and may be signaled in transliteration by linking the letters with a superscript curve.

From an early period the *futhark* was divided into three groups (known as *ættir*) of eight letters each; this led later to the invention of elaborate codes in which a rune is obliquely represented using numbers relating to the group within which it appears and its position there. These numbers may be indicated in a variety of ways, often by a series of offshoots from a central stem or even (more inventively) by fins on one or other side of a fish. Cryptic rune types are most frequently found in manuscripts, but are also used in inscriptions, particularly in Scandinavia. Scandinavian runic inscriptions are cited using the number accorded them by the institute responsible for their registration in each country.

Runes are characters of the runic alphabet, a writing system employed by all Germanic peoples. Different runic scripts are used for different languages. Sweden has the largest number of runic inscriptions (over 3000), followed by Norway and Denmark. Iceland has surprisingly few, given the frequency of references to runes in its literature. Significant numbers of runic inscriptions also survive from Greenland, Germany/Austria, the Isle of Man, Orkney, and England.

The earliest runic inscriptions date from the late 2nd century A.D. Runes continued in use in Scandinavia until well into the medieval period, elsewhere not long after the 11th century. The origins of the runic alphabet, or *futhark* (named after the value of its first six letters, with *th* represented by ᚦ) are unclear. Three main theories still attract support: that the *futhark* was developed ultimately from the Greek, the Northern Italic, or the Roman alphabets.

Runes provide us with much of our earliest evidence concerning the languages of the Germanic peoples, and valuable information about their social history and societal structure. Runes and runic inscriptions are preserved on materials such as stone, wood, metal, and bone. They also appear in manuscripts. Runes were originally designed for inscriptional use, primarily for cutting on wood; hence, the shape of early runes, which avoid curved and horizontal lines.

Transliteration and Terminology

Bold letters are generally used for the transliteration of Continental and Scandinavian inscriptions. Practice varies with Anglo-Saxon inscriptions, but the system devised by Dickins (1932) and adapted by Page (1984; reprinted 1995 with postscript), using spaced letters within inverted commas, has much to commend it.

Runic inscriptions may occasionally be written right-to-left ('retrograde') or 'boustrephedon' (with lines written in alternating directions). Normally there is no word separation, and geminates are simplified.

Occasionally rune cutters ligatured two runes together, perhaps on account of space considerations. The result is a 'bind rune' and may be signaled in transliteration by linking the letters with a superscript curve.

From an early period the *futhark* was divided into three groups (known as *ættir*) of eight letters each; this led later to the invention of elaborate codes in which a rune is obliquely represented using numbers relating to the group within which it appears and its position there. These numbers may be indicated in a variety of ways, often by a series of offshoots from a central stem or even (more inventively) by fins on one or other side of a fish. Cryptic rune types are most frequently found in manuscripts, but are also used in inscriptions, particularly in Scandinavia. Scandinavian runic inscriptions are cited using the number accorded them by the institute responsible for their registration in each country.

Runic Alphabets

Futharks survive from the 5th century, although those from this early period are very rarely complete. They show some diversity of form, but comparison permits reconstruction of the likely shape of the common (older) Germanic *futhark* (Figure 1). It contained 24 letters and was employed in Scandinavia until c. 700 A.D. The order of letters was fixed.

Each rune appears to have had a name as well as a sound value, which generally began with the sound the rune represented. The names are only given in later manuscript sources, in some cases after the alphabet had been reduced and remodeled (see section on Scandinavian alphabets). Some names and meanings are common across all manuscript accounts. So, for example, the name of the L rune ᛚ is recorded as 'lagu' in Old English and 'lǫgr' in the Norwegian Rune Poem. Its reconstructed primitive Germanic form is therefore *laguz 'water.' However, ᚦ is 'thorn' in Old English, but seems to be a word meaning 'giant,' 'monster,' or 'demon' elsewhere. The meaning of some runes is unclear.

The Scandinavian Runic Alphabets

From around the 7th century A.D., the common Germanic *futhark* was extensively remodeled, perhaps first in Denmark. It was reduced from 24 to 16 letters. This alphabet, generally known as the 'younger *futhark*' (properly *futhąrk*), comprises two basic types: the Danish (or common) runes (Figure 2) and the Swedo-Norwegian (or short-twig) runes (Figure 3). Some inscriptions use an admixture of forms from the two varieties (a practice that led to the development of a distinctive futhark in Norway), and there are also variant forms of certain letters within each type. The reasons for the change must in part have been phonetically motivated following a series of sound changes within Old Norse. The resulting system, with no runes for *p, d, g, e,* or *o* but two for closely similar pronunciations of /a/ and /r/, does not appear an obvious improvement. Occasionally the initial sound of the rune itself was affected prompting a change: thus, the *j* rune, primitive Germanic **jēra*, became Old Norse *ār* around the 6th century and therefore came to denote [a]. The *a* rune, ᚬ, represented instead nasalized *a* [ã] following the development of primitive Germanic **ansuz* 'god' to Old Norse *ǫ́ss* (with loss of *n*, nasalization, and compensatory vowel lengthening), but retained its place in the *futhark*, transliterated as **ą**. The development of primitive Germanic *z* (ᛉ) into a strongly palatalized *r* led to a second rune representing *r*, transliterated **R**.

Around 1000 A.D., further modifications to the *futhark* began, with some attempt to address these phonetic inadequacies by a system of dots or points and with a new, Roman alphabetic order to the runes.

The Old English Runic Alphabet

The Old English runic alphabet is known as the *futhorc* (Figure 4). It contains 31 runes. Of these, two are connected with sound changes common to Old English and Frisian. In the case of **ansuz,* rounding took place in Old English and Frisian following the nasalization referred to above, resulting in *ō* (thus **ansuz* → OE *ōs*). In other environments in those languages, West Germanic *a* was fronted to *e* (*æ* in West Saxon). As a result of later sound changes and the development in Old English of West Germanic *ai*, a rune for *a* was still required. The old ᚬ rune was subsequently adopted for *æ* (with a new name *æsc*, 'ash-tree'), and two new runes, found only in Frisian and Old English, introduced: ᚪ for *a* (*ac* 'oak') and ᚩ for *o* (*ōs*). Whether this means that a modified alphabet common to these two peoples was developed on the European continent (as traditionally believed) or whether these similarities resulted instead from

trading contacts between England and Frisia has recently been debated following new theories concerning the relationship between the two languages. Other additions to the Old English runic alphabet (some found only rarely) are the consequence of later sound changes or attempts to represent allophonic variation.

Runic Inscriptions

Surviving runic inscriptions are found on a variety of objects, from large, decorated memorial stones recording the achievements and passing of men and women, to the name of an owner or maker roughly cut on a comb, legends on coins, and graffiti. Early inscriptions employing the common Germanic *futhark* are generally found on portable objects.

Stone Monuments

One of the best known of all runestones is that at Jelling, Denmark, which was commissioned by King Haraldr Gormsson ('Bluetooth'). This large 10th-century stone commemorates the king's parents and lists his own achievements. The Karlevi stone on the Swedish island of Öland celebrates achievements in skaldic verse, requiring knowledge of both runes and the kennings and mythological allusions characteristic of that poetic style to understand its message. Runes would probably have been colored to help them stand out from their background.

In England, the most famous runestone is undoubtedly the Ruthwell Cross (8th century, Northumbrian). It contains extracts, inscribed in runes, from a version of a poem that survives in 11th-century manuscript form as *The Dream of the Rood*. The runes themselves, filling the borders of the two narrow sides of the cross, form part of a complex design involving both runic and roman script, decoration, and carved scenes.

Other Runic Objects

Some runic objects are undoubtedly high status. The 5th-century Gallehus gold horn (one of a pair; now destroyed) recorded the name of its maker in runes around its top. The 8th-century whalebone Franks/Auzon casket from England is composed of intricately carved panels featuring a series of scenes with accompanying runic texts often difficult to interpret.

One finding, however, gives an indication of the quotidian nature of most runic inscriptions. Excavations of the Bryggen district of Bergen, Norway, following a fire in 1955 led to the discovery of over 500 runic inscriptions dating from about 1150 to about 1350, mostly on wood. They include ownership tags, accounting records, poetry, business letters, and personal messages, the most celebrated of which is one that resonates through the ages, apparently from a woman to her mate: 'Gyða says you are to go home.'

Runes and Magic

The association of runes with magic is long-lived, although the evidence for rune-magic is supported far more by literature than by the inscriptions themselves. An unfortunate tendency to assign as 'magical' any inscription that is (or appears) meaningless persists. However, the etymology of Old English *rūn* and its cognates associates the noun with secrecy and mystery, although not necessarily with magic. We learn from the Eddic poem *Hávamál* that the god Óðinn was prepared to sacrifice himself by hanging from a tree for nine days and nights to acquire runic knowledge. A tradition of runic magic is alluded to in many sagas, which show runes being used at times benignly for healing purposes (for example, by the eponymous hero of *Egils saga* in unusually benevolent mood) or with maledictory intent (as in the runes carved by the witch Þurríðr, which lead to the outlaw Grettir's death in *Grettis saga*). *Futharks* inscribed on personal objects such as amulets or weapons may also have had magical significance, particularly as they sometimes appear in combination with words strongly associated with magic, such as **alu** ('luck'), and **laukaR** (literally 'leek,' and perhaps 'prosperity' or 'fertility').

Runes and their Interpretation

Runes present many difficulties of interpretation. It is clear that we must have lost the majority of inscriptions. Those that survive are unlikely to be representative, given the readiness with which wood rots and stone survives.

It can be difficult to distinguish between runes and accidental marks or scratches. Inscriptions on stone, once exposed to the elements, soften and become indistinct; those on other mediums similarly can fracture or become abraded. Our ignorance of the

circumstances (social, individual) leading to the production of an inscription can lead to a multiplicity of interpretations, each of which is necessarily speculative.

Nonspecialists should be encouraged to look at the runes themselves, rather than their transliteration; much can be learned from layout, and certain peculiarities may result from (for example) considerations of space or aesthetics that are not apparent from a printed text. Collaboration between scholars working in various disciplines is vital; numismatists, philologists, art historians, and archaeologists have much to contribute to runic studies, and the best work has been produced by those prepared to consult or collaborate with experts outside their own research area.

Russell, Bertrand (1872–1970)

L C Badon and J W Oller Jr., University of Louisiana, Lafayette, LA, USA

© 2006 Elsevier Ltd. All rights reserved.

Bertrand Russell was born May 18, 1872, in Ravenscroft, Wales, and died February 2, 1970, in Penrhyndeudraeth, Wales. He received his bachelor's degree in mathematics from Trinity College at Cambridge in 1893. He was elected Fellow of the Royal Society in 1908, but in 1916 he was fined £100 and dismissed from Trinity for protesting World War I. He remained a dedicated pacifist throughout his life, though he would deny (Russell, 1951: 35) that this term was an appropriate descriptor. Near the war's end, he was jailed for 5 months for refusing to join the military but was released in September, about 2 months before Armistice Day, November 11, 1918. Russell described his state of mind after the armistice: "Late into the night, I stayed alone in the streets, watching the temper of the crowd .... I felt strangely solitary amid the rejoicings, like a ghost dropped by accident from some other planet .... Always the skeptical intellect, when I have most wished it silent, has whispered doubts to me, has cut me off from the facile enthusiasms of others, and has transported me into a desolate solitude" (1951: 35). Throughout his life Russell (from 1931, the third Earl Russell) remained an elitist, a pacifist, an atheist, and a cynic of wry wit. He received the Nobel Prize for Literature in 1950 and, along with Einstein, advocated unilateral disarmament. He was dismissed twice more after the Trinity firing in 1916, once from City College of New York in 1940 and then from the Barnes Foundation in Pennsylvania in 1943. At age 89, in 1961, he was imprisoned for antinuclear protests for a week, and subsequently he became a vigorous opponent of America's involvement in Vietnam.

Russell's most important contributions to the study of language, and indirectly to linguistics, were grounded in logic and mathematics. In 1901 he discovered what appeared to be a genuine antinomy, that is, an inevitable mathematical paradox. It would become known as Russell's paradox and assured him a place in the history of ideas. It also helped to crystallize his lifelong skepticism. Although he was convinced by his senses that the material world is real, he argued that his faith in the existence of this same world was logically without sufficient justification. In particular, he found fault with the chain of representations and abstractions linking any object of

circumstances (social, individual) leading to the production of an inscription can lead to a multiplicity of interpretations, each of which is necessarily speculative.

Nonspecialists should be encouraged to look at the runes themselves, rather than their transliteration; much can be learned from layout, and certain peculiarities may result from (for example) considerations of space or aesthetics that are not apparent from a printed text. Collaboration between scholars working in various disciplines is vital; numismatists, philologists, art historians, and archaeologists have much to contribute to runic studies, and the best work has been produced by those prepared to consult or collaborate with experts outside their own research area.

Russell, Bertrand (1872–1970)

L C Badon and J W Oller Jr., University of Louisiana, Lafayette, LA, USA

© 2006 Elsevier Ltd. All rights reserved.

Bertrand Russell was born May 18, 1872, in Ravenscroft, Wales, and died February 2, 1970, in Penrhyndeudraeth, Wales. He received his bachelor's degree in mathematics from Trinity College at Cambridge in 1893. He was elected Fellow of the Royal Society in 1908, but in 1916 he was fined £100 and dismissed from Trinity for protesting World War I. He remained a dedicated pacifist throughout his life, though he would deny (Russell, 1951: 35) that this term was an appropriate descriptor. Near the war's end, he was jailed for 5 months for refusing to join the military but was released in September, about 2 months before Armistice Day, November 11, 1918. Russell described his state of mind after the armistice: "Late into the night, I stayed alone in the streets, watching the temper of the crowd .... I felt strangely solitary amid the rejoicings, like a ghost dropped by accident from some other planet .... Always the skeptical intellect, when I have most wished it silent, has whispered doubts to me, has cut me off from the facile enthusiasms of others, and has transported me into a desolate solitude" (1951: 35). Throughout his life Russell (from 1931, the third Earl Russell) remained an elitist, a pacifist, an atheist, and a cynic of wry wit. He received the Nobel Prize for Literature in 1950 and, along with Einstein, advocated unilateral disarmament. He was dismissed twice more after the Trinity firing in 1916, once from City College of New York in 1940 and then from the Barnes Foundation in Pennsylvania in 1943. At age 89, in 1961, he was imprisoned for antinuclear protests for a week, and subsequently he became a vigorous opponent of America's involvement in Vietnam.

Russell's most important contributions to the study of language, and indirectly to linguistics, were grounded in logic and mathematics. In 1901 he discovered what appeared to be a genuine antinomy, that is, an inevitable mathematical paradox. It would become known as Russell's paradox and assured him a place in the history of ideas. It also helped to crystallize his lifelong skepticism. Although he was convinced by his senses that the material world is real, he argued that his faith in the existence of this same world was logically without sufficient justification. In particular, he found fault with the chain of representations and abstractions linking any object of

perception with an abstract conception, or a symbol, of that object.

The widening waves of skepticism owed to Russell's antinomy were to be felt in every field dealing with language, meaning, and truth. The paradox arose from the consideration that some classes seem to contain themselves as members, while others do not. For instance, the class of dogs is not a dog, but the class of classes is certainly a class. A linguistic parallel can be seen in the fact that the word *dog* is not a dog, but the word *word* certainly is a word. By defining a set of all those sets that do not contain themselves as members, Russell came to a mathematical result that turned out upon inspection to be self-contradictory: the defined set could contain itself only if it did not contain itself, but if it contained itself, it could not contain itself. The problem nearly drove a stake in the heart of mathematics. It challenged the hope that reasoning itself can be consistent. It rocked the foundations of epistemology and threatened to topple theories of meaning, reasoning, and language acquisition.

It turned out that Russell's paradox had a linguistic interest, because it was an oblique and austere summary of the language acquisition riddle. How is it possible for an infant to understand words that the infant has not yet learned? Must the infant, like the Baron von Münchhausen, raise itself by its own bootstraps? Is there no logically consistent (non-self-contradictory) escape from the paradoxical fact that language acquisition is evidently possible for naïve infants? How do they do it?

One proposed solution to Russell's paradox was his own, the theory of types. Though criticized as *ad hoc*, it noted that construing a sign as referring to some object or system of objects is a step in a process. If so, a sign under construction can hardly refer to the incomplete system of objects of which it is to be part. For instance, an ordinal number cannot be assigned to the whole system of ordinal numbers, because there is no last or greatest ordinal. Leibniz (1953 [1710]) anticipated this argument in part when he observed that there cannot be a greatest ordinal or a largest figure. Leibniz's extension had to do with the absurdity of applying finite concepts to Almighty God. To pretend to designate any ordinal number as one suited to refer to all ordinals would require reference to the whole set by a sign that is a component of the unfinished construction. The problem resembles the difficulty of meeting yourself on the street before you were born. While writers of fiction can conjure such fantastic self-contradictions, Russell's mathematical objective was to try to find a consistent and complete system of thought that would avoid any such contradictions. The remaining question is whether any such system is possible. Russell noted that the set of all possible ordinals can be referred to from a position above that set, i.e., from a higher level of abstraction. His solution was a hierarchy of distinct types, and it resonated with many logicians, including his student Ludwig Wittgenstein (1918/1922) and, later, P. F. Strawson (1959), Willard van Orman Quine (1960), and other logicians. Though never fully accepted, Russell's solution harmonized with the constructivist approaches to psychological and social theories of cognition as proposed by John Dewey (1938), Jean Piaget (1947, 1981), and Lev Vygotsky (1934/1962).

Russell's theory of types suggested a system of signs built up through layers of abstraction. Chomsky's kernel sentences (1957), used as building blocks for more complex structures, were layered in a sense, and the stratificational models proposed by Lamb (1999) and others were even more so. They were distant theoretical kinfolk, if not direct descendants, of Russell's theory of types. Suppose that an infant begins with basic signs for bodily things and persons and from these basic signs builds layer upon layer to attain higher and more abstract representations. If the higher systems can be shown to have been built up from the more basic signs through a series of layers of increasing abstractness, the language acquisition problem becomes solvable (Oller, 2005).

Related to his contributions to logic and mathematics were Russell's more speculative philosophical writings. In contrast to Reichenbach (1938), who argued that the discovery of meaning depends on the prior discovery of at least some empirical truths, Russell (1940) contended that empirical truths must be based on prior meanings. It was odd that Russell ended up being a materialistic realist in view of the fact that he continued throughout his life to hold that there was by all accounts no logically adequate basis for his faith in the existence of the real world. Russell's problem along that line was first laid out in 1914, when he argued that the existence of the common world cannot be certainly known or inferred from perceptual evidences. This idea was first demolished by John Dewey in 1916 in a book that answered Russell's. Yet Russell clung to the untenable argument and repeated it in his book *Human knowledge* (1948). He supposed that the percept of any object or event is so far removed from its object, and so unlike it in character, as to make the object or event itself problematical.

Dewey followed C. S. Peirce's approach in taking Russell's argument apart piece by piece. Dewey showed that Russell's skepticism was pretentious. In particular, there is no way, Dewey pointed out, to construe a percept or a demonstrative of any kind in a way that would allow the construction of Russell's

problem without presupposing the whole of the material world. In fact, C. S. Peirce (1908) had independently refuted Russell in his argument against the skepticism of David Hume. Peirce showed that if Hume had been merely consistent in his attempt to outlaw 'metaphysical' constructs, Hume would have had to outlaw all reasoning as intrinsically unreasonable. Einstein (1944) independently reached the same conclusion. According to Einstein, Hume's critique "if only carried through consistently, absolutely excludes thinking of any kind" (1944: 289). Einstein also rejected Russell's skepticism about the existence of real objects. Einstein wrote: "I see no danger in taking the thing (the object in the sense of physics) as an independent concept into the system together with the proper spatio-temporal structure" (1944: 291). Einstein agreed with the American pragmatists in their conclusion that "all knowledge about things is exclusively a working-over of the raw-material furnished by the senses" (1944: 283).

Nonetheless, Dewey was solidly among Russell's admiring critics. When they met at Harvard in 1914, Russell said, "To my surprise I liked him very much" (Clark, 1976: 232). In 1916, however, after Dewey demolished Russell's supposedly logical skepticism about the material world, Russell's opinion of Dewey plummeted to something resembling contempt. In 1921 Russell wrote: "In 1914 I liked Dewey better than any other academic American; now I can't stand him" (Clark, 1976: 387). Dewey had become "a man of a large slow-moving mind ... a good man but not a very clever one" (Clark, 1976: 232). When Russell lay nearly dying in Peking, however, it was Dewey, the very man whose "righteousness" Russell detested, who came to his aid (Clark, 1976: 387) and may well have saved his life.

Russenorsk

E H Jahr, Agder University, Kristiansand, Norway

© 2006 Elsevier Ltd. All rights reserved.

The Arctic pidgin Russenorsk (RN), which developed from Norwegian and Russian during the second half of the 18th century, was used in barter trade in northern Norway for around 150 years. RN's main period of use was the 19th century when trading reached large proportions. The sociolinguistic situation in northern Norway during the 19th century was multifaceted and complex, involving many different languages.

RN, now extinct, exhibits several features that make it theoretically interesting. In spite of being formed as a dual-source pidgin – from two Indo-European languages – it shows most of the features common to all pidgin languages. To a stabilized grammatical and lexical core, a variety of lexical items could be added when the situation called for it. It also is noteworthy that RN, unlike most pidgins, was created by socially equal groups of speakers.

Until around 1850, RN enjoyed a high social status, as both fishermen and merchants had to use the pidgin when dealing with the Russians. After 1850, the use of RN was restricted mostly to common fishermen, because the merchants – who constituted the local upper classes – began to spend longer periods of time with colleagues in northern Russia and subsequently developed their own grammatically simplified variety of Russian. As a consequence, RN's social status was devalued.

Today, we have to rely on written material in our study of RN. However, the available texts allow for studies of both lexicon and grammar. They consist of isolated sentences, word lists, and conversations in dialogue form. Altogether, they include some 400 different words, with a core of 150–200 lexemes. Most of them are related to the barter trade. This trade constituted the socioeconomic basis for RN, and when it gradually gave way to cash trade early in the 20th century, the language lost ground and disappeared.

The characteristic features of RN can be summarized as follows:

a. The phonology reflects Norwegian and Russian – however, sounds and consonant clusters not found in both languages are avoided or simplified.
b. 1st and 2nd personal/possessive pronouns are *moja* and *tvoja*.
c. *po* 'on' is the only preposition.
d. *-om* is the general verbal marker (e.g., *kopom* 'buy'), although not always used. Verbs exhibit no markers for tense or person. A special *po*+V construction represents a possible TMA (Tense, Mood, Aspect) device.
e. *-a* tends to mark nouns (e.g., *fiska* 'fish'), which are not inflected and have no plurals.
f. There is no copula.
g. The vocabulary derives mostly from Norwegian and Russian, but contains a number of lexical items from other European languages (e.g., *slipom* 'sleep', from English).
h. RN has SVO syntax. Sentences with adverbial(s) are, however, verb final (e.g., *moja kopom fiska* 'I buy fish'; *moja po tvoja fiska kopom* 'I buy fish from you'). Most sentences are combined paratactically, but embedding is attested. The syntactic possibilities are quite restricted. Most syntactic variation is found in interrogative sentences, RN was used mainly to make inquiries about prices and barter for merchandise.

The Written Language

Diglossia

The adoption of Eastern Christianity in the 10th century brought to the East Slavs the religious language of the Slavs, Old Church Slavonic (OCS), written in Cyrillic.

Syntax, phraseology, and much of the word formation of OCS owed much to Byzantine Greek. In a russified form, OCS served for centuries as the language of 'culture' of the Russians. The earliest extant text is an aprakos Gospel compiled in 1056–1057 by Deacon Grigorij for Prince Ostromir ('Ostromir Gospel'). Secular works – writs, treaties, codes of law (e.g., *Russkaja Pravda* 'Russian Law', mid-11th century, earliest extant copy 1282), etc. – were written in vernacular Russian.

18th Century

Church Slavonic (CS) and Russian now merged to provide the foundation for the modern literary language. Though the everyday language that V. K. Trediakovskij (1703–1769) advocated as a literary language cannot be found in his own writings, he amply demonstrated the word-forming capabilities of CS elements and processes. M. V. Lomonosov (1711–1765) wrote the first complete grammar of Russian as Russian (1757), distinguishing 'high style' forms (i.e., of CS origin) from the rest and insisting elsewhere that CS words were an ineradicable part of Russian.

Writers of the late 18th and early 19th centuries, e.g., N. M. Karamzin (1766–1826) and others, created a 'new style' (*novyj slog*), in which clarity and straight-forwardness were fundamental criteria, eradicating the ponderous, convoluted earlier 18th century prose style. French provided a model for sentence structure and element order. Karamzin himself produced many new words – straight loans, calques (many based on French) and new creations using the resources of Russian.

Thus, modern literary Russian may be said to be at base a blend of a Graecized Church Slavonic, vernacular Russian, and French syntax and order.

Church Slavonic Features

Almost any printed page of modern Russian reveals numerous elements of CS origin. Such are the nominative singular masculine ending of the adjective *-yj/-ij*, the present active participle in *-ushchij*, etc., (and in general the use of participles), suffixes such as *-ie*, *-stvo/-estvo*, *-tel'*, and compound suffixes such as *-enie/-anie/-janie*.

Some morphophonemic alternations show CS origin. For example, CS are *d* ~ *zhd*, *t* ~ *shch* against Russian *d* ~ *zh*, *t* ~ *ch*. Compare *pobedit'* (PRFV) ~ *pobezhdat'* (IMPFV) 'to conquer' with *brodit'* 'to ferment' ~ *brozhenie* 'fermentation,' and *obet* 'promise' ~ *obeshchat'* 'to promise' with *otvetit'* (PRFV) ~ *otvechat'* (IMPFV) 'to answer'. In the striking alternation of pleophonic (*polnoglasnyj*) forms, of Russian origin, and apleophonic (*nepolnoglasnyj*) forms, of CS origin, a vowel *o* or *e* flanks both sides of *l* or *r* in pleophonic forms, whereas a single vowel *a* or *e* follows *l* or *r* in apleophonic forms. Thus, *moloko* 'milk' – *mlekopitajushchij* 'mammalian', *Mlechnyj put'* 'Milky Way'; *korotkij* 'short', *ukorotit'* 'to shorten' – *kratkij* 'brief', *prekratit'* 'to curtail'; *golos* 'voice', *golosovye svjazki* 'vocal cords' – *glasnyj* 'vowel', *soglasnyj* 'consonant'; *bereg* 'bank' – *bregoukre- plenie* 'reinforcement of banks', *bezbrezhnyj* 'boundless'. Pleophonic forms are 'concrete,' mundane; apleophonic forms are 'abstract,' 'learned,' 'technical.'

Phonetics

Old Russian had 12 vowel phonemes and some two dozen consonant phonemes, with open syllables and few clusters. The lapse, from the 12th century, of two ultrashort vowels in certain positions initiated the development toward a language with five vowel phonemes, many more consonant phonemes, many clusters and closed syllables, and a system in which palatalization is largely independent of the following vowel, i.e., is largely phonemic.

The vowels /i, e, a, o, u/ have several allophones each, depending on location of stress, consonantal environment, or the two combined. For example, /a/ – *dast* [dast] 'he will give,' *dal* [dɑ + l] 'gave' MASC, *pjat'* [p̪æt̪] 'five,' *dala* [dɒ'la] 'gave' FEM, *ʉydat'* ['vɨdət̪] 'to give out.'

The accent is not fixed and is mobile, shifting in regular patterns in both declension and conjugation, e.g., *storoná* 'side', ACC *stóronu*, GEN *storoný*, NOM PL *stórony*, GEN PL *storón*, DAT PL *storonám*, etc.

Except as described below, /o/ is replaced in unstressed syllables by /a/, in a system known as *akan'e* 'a-saying' (operating also in southern dialects and Belorussian but not in northern dialects or Ukrainian). Thus 'town' appears as *gorod* /'gorat/ NOM SING, *goroda* / gara'da/ NOM PL, *mezhdugorodnyj* /m̩ʒduga'rodnij/ 'interurban'. The last example also

illustrates *ikan'e* 'i-saying', in which /e/ is replaced in unstressed positions by /i/ (cf. *mezhdu* /'mʲeʒdu/ 'among, between'). *Ikan'e* also affects, in pretonic positions, /a/ after palatalized consonants and /j/, and /o/ after palatalized consonants, /j/ and the palatals /ʃ/ and /ʒ/. Thus, *pjat'* /pʲat/ 'five' ~ *pjati* /pʲi'tʲi/ GEN, *let* /lʲot/ 'flight' ~ *letat'* /lʲi'tat/ 'to fly', *zheny* /'ʒoni/ 'wives' ~ *zhena* /ʒi'na/ 'wife'. The orthography ignores both *akan'e* and *ikan'e*.

There are 13 pairs of distinctively nonpalatalized/palatalized consonants: /p–pʲ/, /b–bʲ/, /m–mʲ/, /f–fʲ/, /v–vʲ/, /t–tʲ/, /d–dʲ/, /s–sʲ/, /z–zʲ/, /n–nʲ/, /l–lʲ/, /r–rʲ/, /k–kʲ/. Consonants /g/ and /x/ have palatalized allophones; /tʃ/ and /ʃʲ/ (realized as [ɕʲ]) are nondistinctively palatalized. In addition, there are /ts/, /ʃ/, /ʒ/, and /j/.

Voiced consonants except sonants are devoiced word-finally and before voiceless consonants. Conversely, voiceless consonants are voiced before voiced consonants except sonants, /v/ and /vʲ/. Nonpalatalized consonants are frequently replaced by corresponding palatalized consonants before palatalized consonants, especially homorganic ones. Apart from a very few items and the devoicing of /z/ in prefixes, (e.g., *raz-* ~ *ras-*, *iz-* ~ *is-*), the orthography entirely ignores the various consonant assimilations and final devoicing. Thus, *otdat'* /ad'datʲ/ 'to give back', *sdelat'* /'zʲdʲelatʲ/ 'to do', *gorod* /'gorat/.

Grammar

Nouns

The Old Russian system of eight declensions, three numbers, and seven cases has been simplified into a system of three principal declensions and a vestigial consonant-stem declension, two numbers, and six cases, the dual number and the vocative case having been discarded.

The 'feminine' declension in *-a/-ja* declines in the singular thus: NOM *komnata* 'room', GEN *komnaty*, DAT *komnate*, ACC *komnatu*, INSTR *komnatoj*, PREP (*v*) *komnate*. A few masculine nouns are found in this declension. A typical noun of the 'masculine' declension is *stol* 'table', *stola, stolu, stol, stolom*, (*na*) *stole*. Neuters decline as masculines except for nominative and accusative, e.g., *okno* 'window', PL *okna* (cf. *stoly*) and, usually, GEN PL – cf. *stolov* – *okon*. One masculine noun is still found in the declension that is now otherwise feminine, illustrated by *chast'* 'part', *chasti*, *chasti*, *chast'*, *chast'ju*, (*o*) *chasti*.

Nouns of the masculine declension denoting animate beings use the genitive as an accusative, thus *muzh* 'husband,' GEN and ACC *muzha*. The genitive-accusative also applies to all nouns denoting animate beings in the plural, of whatever gender: *zhena* – GEN ACC PL *zhen* (/ʒon/).

Remnants of old declensions include an additional genitive in *-u* of some masculine nouns (usually partitive in function): *kilo sakharu* 'a kilo of sugar', cf. *vkus sakhara* 'taste of sugar'; and an extra PREP case in *-ú* of some masculine nouns, having purely locative function: *v lesu* 'in the wood' (cf. *o lese* 'about the wood').

A vestige of the dual probably explains the NOM PL MASC in *-á* instead of *-y*, e.g., *goroda*, cf. *stoly*. The graphic identity of the old NOM dual MASC in *-a* with the GEN SING in *-a* of the same declension has led to the use of the GEN SING of a noun of any gender with the numerals *dva* 'two', *tri* 'three', *chetyre* 'four', and higher numerals ending in these elements. Numeral syntax is further complicated by the use of NOM SING with all numerals ending in *odin* 'one' and GEN PL with all other numerals: *dva stola* 'two tables', *tridtsat' tri stola* '33 tables', *sorok chetyre stola* '44 tables', *sto odin stol* '101 tables', *pjat' stolov* 'five tables'.

The genitive not only is obligatory in negative partitive expressions – *Net otveta* (GEN SING) 'There is no reply', *Deneg* (GEN PL) *ne khvataet* 'There isn't enough money' – but also is more frequent than the accusative with negated transitive verbs – *Shkoly* (GEN SING) *ona ne brosit/Shkolu* (ACC SING) *ona ne brosit* 'She will not give up school'.

Syntactically interesting too is the predicative instrumental, standard with certain copula-like verbs and the future of *byt'* 'to be': *Ona okazalas' /stala/ budet sirotoj* 'She turned out to be /became/ will be an orphan'. With the past tense of *byt'* both the instrumental and the nominative are found: *V to vremja ja byl student*(*om*) 'At that time I was a student', the nominative being more colloquial. *Byt'* has no present tense: *Ona sirota* 'She (is) an orphan'.

There is no article, definite or indefinite. The 'long' form of the adjective, with a declension different from that of nouns, originally expressed 'definiteness' but is now simply the basic form of the adjective and the only attributive form. The 'short' form no longer declines and is restricted to predicative function, where it simply assigns a property to a subject – *Solntse velika, a Zemlja mala* 'The Sun is big but the Earth is small'. The long form is also used predicatively, assigning the subject to a class of like entities. Compare *Vera ochen' umna* (short form) 'Vera is very clever' to *Vera ochen' umnaja* (long form) 'Vera is (a) very clever (person)'. This distinction, while still active, is being eroded, especially in colloquial Russian, in favor of the long form.

Verbs

The aspect system of imperfective versus perfective, already active in Old Russian, has led to the reduction of the multiple tenses of Old Russian to just three: past, IMPFV or PRFV, present, IMPFV only, and future, IMPFV or PRFV. The past, originally a periphrastic participial form, is now reduced to what was the participle and so changes according to gender and number, while present and future have 'true' conjugations of three persons and two numbers, the future imperfective being periphrastic. Thus, 'to infringe' – IMPFV *narushat'*, PRFV *narushit'*: past MASC *narushal/narushil*, FEM *narushala/narushila*, NEUT *narushalo/narushilo*, PL *narushali/narushili*, present *narushaju*, *narushaesh'*, *narushaet*, *narushaem*, *narushaete*, *narushajut*: FUT IMPFV *budu/budesh'/budet/ budem/budete/budut narushat'*, FUT PRFV *narushu, narushish'*, *narushit, narushim, narushite, narushat*. The two aspects are differentiated formally by prefixation, suffixal changes, or a combination of the two and occasionally by suppletion. A complication is the existence of many verbs that are not members of minimal pairs, distinguished only by aspect. These form the groups known as *sposoby dejstvija*, Aktionsarten, 'modes of action'. While associated with a base verb, each Aktionsart, appearing in one aspect only, adds a nuanee to the base verb, without forming a plain aspectual counterpart. For instance, *stuchat'* 'to knock' is IMPFV and has no plain PRFV counterpart; *postuchat'* PRFV is diminutive or attenuative – 'to knock a little / for a short time' and may have to serve in lieu of a plain PRFV; *stuknut'* PRFV is semelfactive – 'to give a single knock'; *zastuchat'* PRFV is inceptive – 'to start to knock'; *prostuchat'* PRFV is perdurative – 'to knock for a certain period of time'; *postukivat'* IMPFV is intermittent (-diminutive) – 'to knock (a little) from time to time'.

The dozen or so pairs of 'verbs of motion,' while participating in the aspect system, also distinguish between determinate (motion in a single direction) and indeterminate (motion not restricted so): *On letel v Moskvu* 'He was flying to Moscow' – *On letal v Moskvu* 'He flew to Moscow (and back, or several times)'.

There are five participles: PRES ACT *narushajushchij* 'infringing', PRES PASS *narushaemyj* 'being infringed', PAST ACT IMPFV *narushavshij* 'were infringing', PRFV *narushivshij* 'having infringed', and PAST PASS PRFV *narushennyj* 'infringed'. They decline as adjectives and the two passive ones have short forms, the PRFV PASS short form being an indispensible component of the passive voice: *Zakon byl narushen*. 'The law was infringed'. The two indeclinable adverbial participles, often called gerunds, are, for example, IMPFV *narushaja* 'infringing' and PRFV *narushiv* (*shí*) 'having infringed'. Subordination by means of participles and gerunds, instead of relative and adverbial clauses, is common.

Lexis

While the bulk of the lexis is Slavonic, Russian has not been averse to borrowing at all periods. From Western European languages Dutch has provided nautical terminology: *botsman* 'bosun', *kil'vater* 'wake'; German – military and other terminology: *lager'* 'camp', *landshaft* 'landscape', *buterbrod* 'sandwich'; French – military, mundane and cultural vocabulary: *batal'on* 'batallion', *pal'to* 'overcoat', *rezhisser* 'producer'; English – nautical terms: *michman* 'midshipman', mundane: *bifshteks* 'steak', industrial: *rel'sy* 'railway lines', sociopolitical: *bojkot* 'boycott', *khuligan* 'hooligan', and in the 20th century, sport: *futbol* 'football', *vindsorfing* 'windsurfing', and technical: *bul'dozer* 'bulldozer', *komp'juter* 'computer'.

Naturally, Russian has gone on exploiting its historically established word-forming processes, but it has also exploited less traditional ones. In this respect, notable are appositional compounds such as *raketa-nositel'* 'carrier rocket,' *dom-muzej* 'home (which is also a) museum', and above all acronyms and various other accreted abbreviations – *vuz* (*vysshee uchebnoe zavedenie*) 'higher educational institution', *GUM* (*Gosudarstvennyj Universal'nyj Magazin*) 'State Department Store', *ROSTA* (*Rossijskoe Telegrafnoe Agentstvo*) 'Russian Telegraph Agency', *kolkhoz* (*kollektivnoe khozjajstvo*) 'collective farm', *univermag* (*universal'nyj magazin*) 'department store', *zarplata* (*zarabotnaja plata*) 'wages', *fizkul'tura* (*fizicheskaja kul'tura*) 'physical training'.

Influence of Russian

In varying degrees, Russian has provided loanwords, especially relating to 20th century life, of technological and cultural significance for many non-Slavonic languages of the former Soviet Union. An extreme case of such borrowing from Russian is provided by Chukchi. In Altaic, North Caucasian, and easterly Uralic languages, subordinating constructions on the Russian model have become common. The languages of many small speech-communities (Ingrian, Veps, Vot, Mordvinian, Siberian languages, etc.) have retreated or are retreating in the face of Russian.

Russian Federation: Language Situation

C Moseley, Caversham, UK

© 2006 Elsevier Ltd. All rights reserved.

The Russian Federation, reconstituted as a state since the collapse of the USSR in 1991, is the homeland of a plethora of languages, but among these Russian itself, the language of the administrative center, occupies an unassailable, dominant position. This was true even when the Union of Soviet Socialist Republics was run from Moscow to administer the 15 individual republics. From its position at the center, the Russian language has bestowed on the minor languages within the Federation's borders a centrally organized education system, literacy, in most case the Cyrillic alphabet itself, and printing facilities – all the accoutrements for the successful propagation of language.

An inherent factor in the Russian language, which favored its propagation, was the relatively small dialect variation within the language. Considering the vast area it covers, Russian has always been – at least since the start of printing in the language – a remarkably homogeneous tongue, so that speakers from Vladivostok in the east and St. Petersburg in the west can readily understand one another. Such dialect variation as exists within Russian can be broadly divided into 'northern' and 'southern' variants. The northern variant grew out of the cultural center of Novgorod, the southern across an area incorporating Tula, Ryazan', and Voronezh.

The Russian language is the most widely spoken representative of the East Slavonic subbranch of the Slavonic branch of the Indo–European language family. The other two members of this branch are Ukrainian and Belarusian (Belarusan). By the 9th century A.D., we can assume that Russian was a distinctive language within this subbranch, but the written language of Kievan Rus was, up to the 14th century, Old Church Slavonic (Slavonic, Old Church), which stemmed from South Slavonic languages. The Cyrillic alphabet as used in that language, though it did not correspond well with the divergent sound system of East Slavonic, remained in use as the standard orthography from the beginnings of recorded writing in Russian, which coincided with the country's conversion to Christianity around the year 988, right up to the time of Peter the Great (1672–1725).

The first writings of the medieval period were translations from Greek liturgy and scripture into Old Church Slavonic. The centers of learning were mainly Kiev and Novgorod at first, but the creation of literature spread to such centers as Pskov and Ryazan' and, after the introduction of printing, primarily to Moscow. The first homegrown printed book known in Russia is a book of religious epistles dated 1564.

Russian has not, however, had an entirely phonetic spelling system, despite a process of orthographic simplification; for instance, the phenomenon of *akanye* or reduction of [o] to a schwa or [a] in unstressed syllables is a feature whose general spread within Russian predates the simplification of the Cyrillic alphabet as adapted to Russian use. This process began with the 'civic alphabet' introduced under Tsar Peter I in 1710.

Codification of the modern Russian language may be said to have really begun with the Russian Grammar by the great scholar Lomonosov, published in 1755. Within two generations of this, the great flowering of classical Russian literature had begun, Pushkin being the earliest acknowledged master. The alphabet was further simplified away from the conservative Old Church Slavonic script by the abolition of some redundant letters in 1917–1918 (**Figure 1**), in the first year after the October Revolution – though not as a result of it, but rather as the outcome of reforms proposed by an imperial orthographic commission.

The Cyrillic alphabet does adequately and systematically reflect the extensive phenomenon of

Russian Federation: Language Situation

C Moseley, Caversham, UK

© 2006 Elsevier Ltd. All rights reserved.

The Russian Federation, reconstituted as a state since the collapse of the USSR in 1991, is the homeland of a plethora of languages, but among these Russian itself, the language of the administrative center, occupies an unassailable, dominant position. This was true even when the Union of Soviet Socialist Republics was run from Moscow to administer the 15 individual republics. From its position at the center, the Russian language has bestowed on the minor languages within the Federation's borders a centrally organized education system, literacy, in most case the Cyrillic alphabet itself, and printing facilities – all the accoutrements for the successful propagation of language.

An inherent factor in the Russian language, which favored its propagation, was the relatively small dialect variation within the language. Considering the vast area it covers, Russian has always been – at least since the start of printing in the language – a remarkably homogeneous tongue, so that speakers from Vladivostok in the east and St. Petersburg in the west can readily understand one another. Such dialect variation as exists within Russian can be broadly divided into 'northern' and 'southern' variants. The northern variant grew out of the cultural center of Novgorod, the southern across an area incorporating Tula, Ryazan', and Voronezh.

The Russian language is the most widely spoken representative of the East Slavonic subbranch of the Slavonic branch of the Indo–European language family. The other two members of this branch are Ukrainian and Belarusian (Belarusan). By the 9th century A.D., we can assume that Russian was a distinctive language within this subbranch, but the written language of Kievan Rus was, up to the 14th century, Old Church Slavonic (Slavonic, Old Church), which stemmed from South Slavonic languages. The Cyrillic alphabet as used in that language, though it did not correspond well with the divergent sound system of East Slavonic, remained in use as the standard orthography from the beginnings of recorded writing in Russian, which coincided with the country's conversion to Christianity around the year 988, right up to the time of Peter the Great (1672–1725).

The first writings of the medieval period were translations from Greek liturgy and scripture into Old Church Slavonic. The centers of learning were mainly Kiev and Novgorod at first, but the creation of literature spread to such centers as Pskov and Ryazan' and, after the introduction of printing, primarily to Moscow. The first homegrown printed book known in Russia is a book of religious epistles dated 1564.

Russian has not, however, had an entirely phonetic spelling system, despite a process of orthographic simplification; for instance, the phenomenon of *akanye* or reduction of [o] to a schwa or [a] in unstressed syllables is a feature whose general spread within Russian predates the simplification of the Cyrillic alphabet as adapted to Russian use. This process began with the 'civic alphabet' introduced under Tsar Peter I in 1710.

Codification of the modern Russian language may be said to have really begun with the Russian Grammar by the great scholar Lomonosov, published in 1755. Within two generations of this, the great flowering of classical Russian literature had begun, Pushkin being the earliest acknowledged master. The alphabet was further simplified away from the conservative Old Church Slavonic script by the abolition of some redundant letters in 1917–1918 (**Figure 1**), in the first year after the October Revolution – though not as a result of it, but rather as the outcome of reforms proposed by an imperial orthographic commission.

The Cyrillic alphabet does adequately and systematically reflect the extensive phenomenon of

а б в г д е ж з и й к л м н о п р с т у ф х ц ч ш щ ъ ы ь э ю я
a b v g d ye zh z i I k l m n o p r s t u f kh ts ch sh shch * y ** e yu ya
* nonpalatalization of preceding consonant
** palatalization of preceding consonant

Figure 1 The Cyrillic alphabet as used in modern Russian (abolished redundant letters in brackets) with their phonetic values.

palatalization in the language, with separate sets of 'palatalized' and 'unpalatalized' vowels, and predictable rules for palatalizing after particular consonants, but it hardly reflects the stress pattern at all. Stress in Russian is unpredictable, with emphasis occurring on any syllable (even varying among different inflections of the same word) and implying the 'reduction' of unstressed vowels in neighboring syllables.

Features of the Language

As mentioned, dialect variation within Russian is not great, and grammatical and pronunciation differences from the standard language tend to be minor. Differences are mainly lexical and are chiefly associated with cultural, mainly agricultural and domestic, terminology (for example, northern *boronovat'*, southern *skorodit'* 'harrow' (v.), northern *kuznets*, southern *koval'* 'smith'). The grammatical structure of Russian varies little from the standard across the country.

Russian is typical of the Slavonic languages in having three genders (masculine, feminine, and neuter) and an extensive noun case system by Indo–European standards. Six cases are in active use: nominative, accusative, genitive, dative, instrumental, and prepositional. Also characteristic is the 'partitive genitive' formation used for negating the verb 'to be' (in a location or in possession). The pronoun system is fully declinable in the six cases as well.

Another typical Slavonic feature is the aspectual system of verbs. While there are only two simple synthetic tenses (present and past, or more accurately, nonpast and past), there are also two aspects: perfective and imperfective. Perfective forms of the verb are used to indicate completed or finite single actions, whereas the imperfective forms tend to indicate continuing or repeated action (*prinimat'* (impf.) 'to receive' (= be receiving), *prinyat'* (pf.) 'to receive' (= have received). Perfective forms are mostly created by adding prefixes to the verb stem, but with some verbs, an imperfective form is created by adding a suffix to a basic (perfective) stem, or by altering the final vowel of the stem.

Characteristic of Russian and East Slavonic is the use of participles to replace relative pronouns in relative clauses (*vvidu nravov, tsarivshikh* . . . 'in view of the customs [that were] prevailing . . .').

As with many other Indo–European languages, the prepositions take a range of specific cases, for example, *zhena* 'wife' (nom.), *o zhene* (locative/prepositional) 'about the wife.'

Russian word order within the clause is very free and is adaptable for different nuances of emphasis. Subject–Verb–Object is common, but any variation on these is possible, owing to the relations within the clause or phrase being shown by the case-agreement system.

Language Policy in Russia

The pre-Revolutionary Russian Empire actively suppressed the use of minority languages (with the exception of Finland, Russian Poland, and the Baltic provinces (where German (German, Standard) was the medium of educated and official intercourse). Even nations with sizeable populations were forbidden the official use of their native tongues – Ukrainian was banned in Ukraine from 1876 to 1905, for fear of secessionism. Among the smaller non-Christian peoples of the Empire, Russian was also a medium of missionary expansion, though to some extent Bible translation and literacy were permitted among non-Orthodox nations.

After 1917, and the creation of the Union of Soviet Socialist Republics, the central policy changed markedly. Equality of languages within the new union, with no position of primacy accorded to Russian, was the lofty stated aim of Lenin's early administration, but the practical problems of providing teaching and literature and real official support for the languages of the smaller minorities led to certain inevitable compromises with this ideal. For a start, centralization of the new state in the Russian capital, the administrative center of a command economy, meant that, in effect, Russian became the lingua franca of the Soviet Union.

Nevertheless, the early years of the Soviet state saw energetic campaigning for Union-wide literacy and all that this implied. It was a stimulus for linguistic research, especially among the languages of the far North, in order to create viable orthographies.

The Russian orthography was itself simplified after 1918, with the removal of letters which no longer served a phonetic function. For languages – Turkish, Caucasian, and Indo–Aryan – of the Islamic peoples of the USSR, at first a modified Arabic script was devised, but this was abandoned within a few years in favor of a Latin-based model, as a compromise between Cyrillic and Arabic. Such scripts were devised even for very small languages of the union, such as the tiny Finno–Ugrian Veps community. Devising orthographies often meant an arbitrary choice of a particular dialect as the standard, especially among sparse, widely scattered speech communities.

This policy of standardizing languages within the Soviet Union was a selective one. Some smaller languages remained unwritten – some languages of the Caucasus and Pamirs, for instance. Such situations were usually accompanied by widespread bilingualism or multilingualism on the part of the speakers, and an assimilationist policy by the authorities.

'Assimilation' in Soviet times was to some extent a relative term, and in the later years was less aggressively pursued than in the Stalin era and the decade thereafter. Ethnic assimilation, or dilution, was effected as part of the mass migration policies (the deportations under Stalin of large portions of, or virtually entire, ethnic groups; immigration of Russian laborers and their families into republics undergoing heavy industrialization). While on the one hand, the proportion of native speakers of a minority language might be heavily diluted, an education policy was widely pursued that, at least nominally, offered a choice between a Russian- and a native-language education. Literacy, in both Russian and non-Russian languages, made huge strides forward under the Soviets compared with Tsarist times. Whereas 28.4% of the Russian Empire's population of school age and beyond was literate in 1897, by 1970 the figure was 99.7%, according to census figures.

Within the borders of the present-day Russian Federation there is a wide proliferation of languages belonging to several different linguistic families: Indo–European, Altaic, Uralic and Caucasian – at least 70 distinct languages in all. The present Russian Federation has inherited the legacy of the Soviet Union as regards the language policy of its constituent republics. The Russian language has left a heavy imprint on the lexical content, syntax, and grammar of these languages, regardless of how divergent they are from Slavic structure. Furthermore, although Soviet policy had set so many of the minority languages on the path to literacy, the infrastructure to implement it was not uniformly applied throughout the USSR, and now such infrastructure as there is has been left to its own devices or to the legislatures of the constituent republics. Objective factors such as remoteness from Moscow and sparseness of population (such as Yakutia) and proportions of Russians to natives (for example, Chuvashia, nearly entirely Chuvash, or Karelia, predominantly Russian), have an important part to play. Then there is the problem of dialect diversity in nonstandardized languages. For example, although the 318 000 speakers of Buryat (Buriat, China) make up 90% of the population of the titular Buryat republic, the language is spoken in a range of variants beyond its borders, in Mongolia and China, which differ from the 'literary' language of the Irkutsk area. The spoken language is the Khori dialect, but even in Ulan-Ude, the capital, Russian has a cohesive role to play as a common second language. And Buryat is by no means the most diverse language in Russia in terms of dialects.

Outside the borders of the present-day Russian Federation, Russian speakers can primarily be counted among the descendants of Russian populations who migrated to neighboring republics within the USSR in Soviet times or were already settled there. According to *Ethnologue* (2000), the current numbers of Russian speakers in former republics of the USSR, now the Confederation of Independent States (CIS), plus the Baltic republics are as follows (rounded off to the nearest thousand):

Armenia: 70 000 out of 3 536 000
Azerbaijan: 475 000 out of 7 669 000
Belarus: 1 134 000 out of 10 315 000
Estonia: 468 000 out of 1 476 000
Georgia: 372 000 out of 5 059 000
Kazakhstan: 6 227 000 out of 16 219 000
Kyrgyzstan: 1 409 000 out of 4 643 000
Latvia: 862 000 out of 2 424 000
Lithuania: 344 000 out of 3 694 000
Moldova: 562 000 out of 4 378 000
Tajikistan: 237 000 out of 6 015 000
Turkmenistan: 349 000 out of 4 309 000
Ukraine: 11 335 000 out of 50 861 000
Uzbekistan: 1 661 000 out of 23 574 000

Thus it can be seen that the numbers of Russians outside the immediate borders of Russia are sizeable. In absolute terms, the greatest number is found in Ukraine, followed by Kazakhstan; in terms of proportions, Russians are found in greatest numbers in Latvia and Estonia. Their influence on the economic and social life of those countries is strong enough for the present Russian government to use them as a powerful bargaining lever in intergovernmental relations, in defense of their ethnic institutions, their economic power base, and notably the maintenance of the Russian language in education and public life, acutely at loggerheads with the nation-building

efforts of newly independent states. Russian influence is less marked in the Central Asian republics, with the notable exception of Kazakhstan, a nation which was heavily industrialized and exploited during the Soviet period.

Russian diaspora are found, generally in much smaller numbers, further abroad. Jewish emigration to Israel from Russia in the later decades of the Soviet period and subsequently has resulted in a very sizeable Russian-speaking population of 750 000 (*Ethnologue*, 2000). It was for religious reasons, too, that some of the smaller and older-established Russian-speaking populations emigrated to the New World – such as the Doukhobors, a conservative Orthodox sect which left for the United States and Canada over a century ago. But these Russian populations in North America are dwarfed in size by the considerable waves of more recent emigrants.

Russian Formalism

R Le Huenen, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Formalism emerged from discussions between two small groups of young Russian scholars: the Moscow Linguistic Circle, which was founded in 1915 by Roman Jakobson, Grigorii Vinokur, and Petr Bogatyrev, and the OPOIAZ (Society for the Study of Poetic Language), which was established 1 year later in Petrograd (St. Petersburg) by literary scholars, including Victor Shklovskii, Iuri Tynianov, Boris Eikhenbaum, Boris Tomashevskii, Lev Iakubinskii, Osip Brik, and Victor Vinogradov. The term 'Formalist' was coined by opponents to the movement. Formalists themselves, especially Eikhenbaum ('The theory of the "Formal" method,' 1927), expressed strong opposition at the time about what they perceived to be a reductive appreciation of their work. On the contrary, they subscribed to a dynamic approach to literature, emphasizing a commitment to a science of literature rather than a concern for methodology alone. Between 1916 and 1923, the activities of the two groups led to the publication of six volumes of *Studies on the theory of poetic language* (*Sborniki po teorii poeticheskogo iazyka*).

Literary Criticism in Russia at the Time of the Formalists

Russian Formalism was a reaction against academic research, which used antiquated aesthetic, psychological, and historical axioms and had lost sight, in the words of Eikhenbaum ('Theory'), of its own subject and was unable to renew itself through a real understanding of theoretical problems. The Formalists were also united against the type of impressionistic criticism produced by journalists insofar as journalism had appropriated, during the last decades of the 19th century, the field of literary criticism ignored by unproductive scholars only concerned with sociopolitical issues. The Formalists insisted on the specific character of the literary text and on the need to examine it solely on literary grounds, without having to take into account the external conditions, biographical, psychological, or historical, that prevailed at the time of creation. On the other hand, most literary journalists were followers of the Symbolist movement and resorted to a kind of aesthetic subjectivism that the Formalists found unsuitable and ineffective in comparison with the diversity of the historical facts and the complexity of the stylistic devices displayed in a literary work. In addition, the Formalists were critical of the philosophical and religious language used by the Symbolists and opposed the theory, supported by the latter, of harmonizing form and content.

Although they remained indebted to literary and linguistic theoreticians such as Aleksandr Veselovskii (1838–1906) and Aleksandr Potebnia (1835–1881), the Formalists dismissed the ethnographic character of the genetic approach developed by the former, and the well-known view of the latter that "art is thinking in images." Genetic interpretations may throw light on the origin of a literary phenomenon, but they fail to account for the specific use of techniques and devices

efforts of newly independent states. Russian influence is less marked in the Central Asian republics, with the notable exception of Kazakhstan, a nation which was heavily industrialized and exploited during the Soviet period.

Russian diaspora are found, generally in much smaller numbers, further abroad. Jewish emigration to Israel from Russia in the later decades of the Soviet period and subsequently has resulted in a very sizeable Russian-speaking population of 750 000 (*Ethnologue*, 2000). It was for religious reasons, too, that some of the smaller and older-established Russian-speaking populations emigrated to the New World – such as the Doukhobors, a conservative Orthodox sect which left for the United States and Canada over a century ago. But these Russian populations in North America are dwarfed in size by the considerable waves of more recent emigrants.

Formalism emerged from discussions between two small groups of young Russian scholars: the Moscow Linguistic Circle, which was founded in 1915 by Roman Jakobson, Grigorii Vinokur, and Petr Bogatyrev, and the OPOIAZ (Society for the Study of Poetic Language), which was established 1 year later in Petrograd (St. Petersburg) by literary scholars, including Victor Shklovskii, Iuri Tynianov, Boris Eikhenbaum, Boris Tomashevskii, Lev Iakubinskii, Osip Brik, and Victor Vinogradov. The term 'Formalist' was coined by opponents to the movement. Formalists themselves, especially Eikhenbaum ('The theory of the "Formal" method,' 1927), expressed strong opposition at the time about what they perceived to be a reductive appreciation of their work. On the contrary, they subscribed to a dynamic approach to literature, emphasizing a commitment to a science of literature rather than a concern for methodology alone. Between 1916 and 1923, the activities of the two groups led to the publication of six volumes of *Studies on the theory of poetic language* (*Sborniki po teorii poeticheskogo iazyka*).

Literary Criticism in Russia at the Time of the Formalists

Russian Formalism was a reaction against academic research, which used antiquated aesthetic, psychological, and historical axioms and had lost sight, in the words of Eikhenbaum ('Theory'), of its own subject and was unable to renew itself through a real understanding of theoretical problems. The Formalists were also united against the type of impressionistic criticism produced by journalists insofar as journalism had appropriated, during the last decades of the 19th century, the field of literary criticism ignored by unproductive scholars only concerned with sociopolitical issues. The Formalists insisted on the specific character of the literary text and on the need to examine it solely on literary grounds, without having to take into account the external conditions, biographical, psychological, or historical, that prevailed at the time of creation. On the other hand, most literary journalists were followers of the Symbolist movement and resorted to a kind of aesthetic subjectivism that the Formalists found unsuitable and ineffective in comparison with the diversity of the historical facts and the complexity of the stylistic devices displayed in a literary work. In addition, the Formalists were critical of the philosophical and religious language used by the Symbolists and opposed the theory, supported by the latter, of harmonizing form and content.

Although they remained indebted to literary and linguistic theoreticians such as Aleksandr Veselovskii (1838–1906) and Aleksandr Potebnia (1835–1881), the Formalists dismissed the ethnographic character of the genetic approach developed by the former, and the well-known view of the latter that "art is thinking in images." Genetic interpretations may throw light on the origin of a literary phenomenon, but they fail to account for the specific use of techniques and devices

that organize, for instance, the basic raw material of a narrative (its contingent events) into a formal and artistic construct, insofar as a work of literature is not a mere accumulation of devices but an organized whole. Shklovskii rejected Potebnia's contention that "without imagery there is no art," arguing that images change little, that the same image can be found "from century to century, from nation to nation, from poet to poet" ('Art as device', 1917), and that images alone are less important than the techniques used by writers to produce them. Shklovskii also pointed out that images are common in both everyday and poetic language, and stressed Potebnia's unawareness of two aspects of imagery: "imagery as a practical means of thinking . . . and imagery as poetic, as a means of reinforcing an impression."

In its early stage, Russian Formalism was closely linked to the Futurist avant-garde movement (Vladimir Mayakovsky, Victor Khlebnikov, Aleksei Kruchenykh, and David Burlyuk, among others). Experimenting with language and especially the texture of sound, the Futurists attempted to create a new form of poetry directed against the Symbolist commitment to subjectivism. The notion of how form in itself can be expressive or meaningful, even in the absence of verbal meaning, was particularly appealing to the Formalists (Shklovskii's 'On poetry and trans-sense language,' 1916, and Jakobson's Khlebnikov's 'Poetic language,' 1919). The Formalists did not endorse the traditional dichotomy between content and form in the literary work, because they viewed content as expressed only through a certain formal arrangement, which becomes identified with it. Instead, they emphasized the difference between **material** and **device** – that is, between the protogenetic stage of the literary process and its constructive or creative stage. The organizational principles of that process transform the raw material into an aesthetic work through such devices as sound texture, rhythm, syntax, and plot features.

Literariness

Literariness (*literaturnost'*), a key concept for the Formalists, laid the ground for a science of literature. "The object of study in literary science is not literature but 'literariness,' that is, what makes a given work a literary work. [. . .] The historians of literature have helped themselves to everything – environment, psychology, politics, philosophy. Instead of a science of literature, they have worked up a concoction of homemade disciplines. They seem to have forgotten that those subjects pertain to their own fields of study" (R. Jakobson, *Modern Russian poetry*, 1921). Eikhenbaum stressed the importance of acknowledging the specific features of the literary object and its uniqueness in comparison with all other cultural or artistic products. According to Shklovskii, literariness was an effect resulting from the process of **defamiliarization** (*ostranenie*). Claiming that art is a way of perceiving the artfulness in an object, Shklovskii inferred that the object alone is not important, that the aim of art is to make objects **unfamiliar** by increasing the difficulty and duration of perceptual effect and thereby hindering the reader's ability to relate to objects, situations, and texts in a familiar and automatic manner. Tolstoy, for instance, created an effect of defamiliarization by not naming the familiar object: in *Shame*, he did not use the word 'flogging' but instead provided a full description of the act as if it were an extraordinary and unprecedented event. In his study of Lawrence Sterne's *Tristram Shandy*, Shklovskii associated with defamiliarization the 'laying bare' of the literary techniques – the narrator's commentaries on the structure of the novel.

Poetic and Everyday Language

In attempting to define literariness, the Formalists established a clear distinction between poetic and practical language (or everyday usage) and attached to the former the essential property of art. Concentrating on the analysis of the 'phonic texture' of poems, they followed the Futurists in arguing in favor of the primacy of sound over meaning in poetry. In addition, rhythm became, for Tomashevskii (Eikhenbaum, 'Theory'), the foundation for a theory of verse that would regulate the other formal components of poetic discourse, be it classical metrics or any rhythmic pattern. Whereas everyday language aims at efficient communication, poetic language emphasizes artistic self-consciousness, refers to its own composition rather than to objects or signifieds. In the words of Jakobson, it exerts an organized coercion on the mind of the reader, whose attention is drawn to the constructed formation of the poem. However, during the middle phase of Russian Formalism (1919–1924), the realization that poetry could not be reduced to its phonic features led the Formalists to reevaluate their views on verse and to reintroduce in their analysis considerations related to syntax and semantics (Eikhenbaum, *Melody of Russian lyric verse*, 1922; Tynianov, *The problem of verse language*, 1924; Brik, 'Rhythm and syntax,' 1927).

Story and Plot

The Formalists distinguished between two levels of narrative: story (*fabula*) and plot (*siuzhet*). Story defines a series of events connected through

chronological and causal links, whereas plot consists of the narrator's rearrangement of them without necessarily observing such determining factors. Plot includes other elements as well, such as comments and digressions. In fact, the plot, or *siuzhet* construction, is the defamiliarizing narrative counterpart of the story (*fabula*). According to Shklovskii, typical categories of plot composition are the 'staircase' (repetition and parallelism are used in relating events), the 'hooklike' structure (where contrast and opposition prevail, leading to a false ending), and double plotting (a combination of heterogeneous components). Plot construction is generally realistically motivated, or unmotivated, 'laid bare,' as in Sterne's *Tristram Shandy*, impeding the reader's expectations by means of continuous interruptions of the action, delays, authorial digressions, and various types of chronological shifting (Shklovskii, 'Sterne's Tristram Shandy,' 1921). Gérard Genette's more recent narratological distinction between *diégèse* and *récit* is clearly based on the *fabula/siuzhet* dichotomy.

Literary Evolution

In the late period of Russian Formalism (1924–1930), there emerged the realization that literature and language should be examined not simply on synchronic grounds as poetic devices but within their diachronic developments as well. It became clear to Tynianov ('On literary evolution,' 1927) that the very existence of a literary fact owes much to the interaction of both literary and nonliterary systems, and how important it is to stress the link between literature and social conventions (*byt*). In a 1928 article, 'Problems in the study of literature and language,' written jointly with Jakobson, Tynianov returned to the question of literary evolution by arguing that literature is part of a complex network of interrelated systems, each of which is regulated by its own internal laws and correlated to other systems through a finite series of structural laws. Therefore, the study of literature as a dynamic process entails two consecutive moves: the need to establish the specific laws that govern the literary text conceived as an immanent structure, followed by the analysis of possible correlations between literature and other systems of meaning. However, Tynianov and Jakobson's views were generally seen as isolated attempts to connect literature and culture, whereas Russian Formalism by and large remained committed to the notion of literariness and to literature as holding a unique place among cultural and artistic objects.

The Critique, Suppression, and Influence of Russian Formalism

In 1928 Formalism faced a serious critique in the form of an article, 'The formal method in literary scholarship,' that was signed by Pavel Medvedev but is now attributed to Mikhail Bakhtin. Formalists were attacked for providing neither a sociological nor a philosophical justification for their theories and for not addressing social and ideological issues. This criticism was echoed by the Soviet regime, namely by Leon Trotsky in his book *Literature and revolution* (1923) and by Anatolii Lunacharskii in an essay titled 'Formalism in the theory of art' (1924). As the attacks intensified, Shklovskii was forced to yield to political pressure and in 1930 produced a self-critical statement, 'A monument to a scientific error,' that harshly criticized the assumptions of Formalist theory. However, the Formalist movement had lost its momentum by that time: the Moscow Linguistic Circle had been dissolved in 1920 after the departure of Roman Jakobson and Petr Bogatyrev for Prague, and OPOIAZ had broken up in 1923.

Russian Formalism continued to exert influence abroad, through the Prague Linguistic Circle (Roman Jakobson, Petr Bogatyrev, Vilém Mathesius, Jan Mukařovsky), the Polish 'integral' school in the 1930s (Manfred Kridl), and the French Structuralist school in the 1960s (Greimas, Genette, Barthes, Todorov, Brémond), which became acquainted with Formalist principles through the publication of Tzvetan Todorov's anthology *Théorie de la littérature: textes des formalistes russes* (1965), with a preface by Roman Jakobson. The French Structuralists shared with the Russian Formalists the view that the study of literature had to be conducted in accordance with linguistic principles and methodology and that the literary text was an autonomous system to be apprehended only through an immanent process of reading.

In the early 1960s, some of the earlier Formalist studies were republished in the Soviet Union, and the appearance of the Moscow-Tartu School of Semiotics (Viacheslav Ivanov, Iurii Lotman, Boris Uspenskii), with its emphasis upon language and meaning generated as sign systems, may be seen as a new and revitalized brand of both Formalism and Structuralism.

Origins of Russian Lexicography

Lexicography in Russia, as in many other European countries, originated in the Middle Ages (Kovtun, 1963).

Glossaries in the 13th century were mainly collections of difficult words, very often including proper names from the Bible and ancient Russian manuscripts. Strictly speaking, they were lists of difficult words called азбуковник 'alphabetic lists'. In the 16th–17th centuries they were frequently revised and laid the basis for more profound lexicographic projects (Kovtun, 1977). In the 18th century, A. Schichkov and A. Vostokov made significant attempts to undertake dictionary making as a serious scientific process (Bogatova, 2000).

Major Dictionaries of the 18th, 19th, and 20th Centuries

The Pre-Revolutionary Period

The end of the 18th century was marked by growing interest in vernacular languages, and Russian philological studies focused on creating a serious dictionary of Russian as a literary language. When in 1783 the Russian Academy was established, the first large dictionary of the contemporary language, in six volumes, was compiled (RAD), which appeared in 1789 (Словарь Русской Академии (*Dictionary of the Russian Academy*), 1789–1794).

It was aimed at revealing the system of the language, but the Russian written language had two forms: Russian itself and Old Church Slavonic. Therefore an entry in RAD had certain essential peculiarities: Its lexicosemantic abstraction covered the semantic units of both Russian and Old Church Slavonic. The Slavonic vocabulary in RAD exceeds the number of Slavonic words (and meanings) that circulated in the high and middle levels of the Russian written language. At the end of the 18th century, Russian and Slavonic were still united in the linguistic consciousness of their speakers. The notion of 'exemplary language' and correct literary word use was traditionally associated with the books of the Old Church Slavonic written language.

RAD was revised in 1806–1822, based on *a new alphabetical order*. Although revised, it did not reflect changes in the living language. This scholastic feature was typical of all early academic dictionaries, although they played an important role in society.

Origins of Russian Lexicography

Lexicography in Russia, as in many other European countries, originated in the Middle Ages (Kovtun, 1963).

Glossaries in the 13th century were mainly collections of difficult words, very often including proper names from the Bible and ancient Russian manuscripts. Strictly speaking, they were lists of difficult words called азбуковник 'alphabetic lists'. In the 16th–17th centuries they were frequently revised and laid the basis for more profound lexicographic projects (Kovtun, 1977). In the 18th century, A. Schichkov and A. Vostokov made significant attempts to undertake dictionary making as a serious scientific process (Bogatova, 2000).

Major Dictionaries of the 18th, 19th, and 20th Centuries

The Pre-Revolutionary Period

The end of the 18th century was marked by growing interest in vernacular languages, and Russian philological studies focused on creating a serious dictionary of Russian as a literary language. When in 1783 the Russian Academy was established, the first large dictionary of the contemporary language, in six volumes, was compiled (RAD), which appeared in 1789 (Словарь Русской Академии (*Dictionary of the Russian Academy*), 1789–1794).

It was aimed at revealing the system of the language, but the Russian written language had two forms: Russian itself and Old Church Slavonic. Therefore an entry in RAD had certain essential peculiarities: Its lexicosemantic abstraction covered the semantic units of both Russian and Old Church Slavonic. The Slavonic vocabulary in RAD exceeds the number of Slavonic words (and meanings) that circulated in the high and middle levels of the Russian written language. At the end of the 18th century, Russian and Slavonic were still united in the linguistic consciousness of their speakers. The notion of 'exemplary language' and correct literary word use was traditionally associated with the books of the Old Church Slavonic written language.

RAD was revised in 1806–1822, based on *a new alphabetical order*. Although revised, it did not reflect changes in the living language. This scholastic feature was typical of all early academic dictionaries, although they played an important role in society.

In 1847, a new academic dictionary project in four volumes was launched, entitled Словарь Церковно-Славянского и Русского Языка (*A dictionary of the Church Slavonic and Russian languages*). This dictionary showed selected philological parameters of the vocabulary, including syntactic and phonetic features associated with each word. Positive features of this dictionary included differentiated word-forming and orthographic variants of lexemes, along with distinction of homonyms by means of language signs. Moreover, the definitions were based on the principles of linguistic analysis.

The second academic dictionary entitled Словарь Церковно-Славянского и Русского Языка (*A dictionary of Church Slavonic and Russian languages*) was planned and developed as 'a treasury of the language' according to contemporary scientific standards. It contained, along with words from early manuscripts, words extracted from the latest literary works. The number of foreign words as well as new terms from science and the arts were considerably increased compared to its predecessors. However, this work did not become a thesaurus as planned, because its compilers were more concerned with applying prescriptive principles of word and definition selection. Thus, only neologisms that were in general use in the literary language were introduced into the dictionary, and all the rest were left out.

Simultaneously, the Second Department of the Academy began to work on a dictionary of Russian popular dialects. *Outline of a regional dictionary of the great Russian language* appeared in 1852. Six years later, a supplement edited by A. Vostokov was published. Both editions were based on the *principle of differentiation*, and they laid the basis for dictionaries of Russian dialects that appeared in the 20th century.

The system of Russian dictionaries compiled in the Academy was oriented mainly towards the history of the language. The Second Department of the Academy had a great linguistic goal—to demarcate Old Church Slavonic and Russian, showing the points of maximum agreement, and to indicate the results of their long interaction. In 1858–1861, Словарь Церковно-Славянского Языка (*A dictionary of the Church Slavonic language*) was published in two volumes. It provided the necessary linguistic tools to discern between the two language systems.

The third Словарь Академии (*Academy dictionary*), edited by Y. Grot, appeared in 1895; for the first time, a dictionary undertook a description of modern Russian language. The fundamental links between word meaning and word use are described. After Grot's death, the dictionary was supervised and edited by A. Shakhmatov.

The 'Shakhmatov era' of Russian academic lexicography is frequently considered to be its peak. According to Shakhmatov's theory, the basis for the description of the national language must be a living language with a mixture of written and spoken languages.

The dictionary became a treasury of living Russian words and even now is considered to be a major milestone in Russian lexicography. It evidenced the connection between different parts of the Russian national language as well as the influence of dialects on the literary language. Shakhmatov's dictionary is recognized among Russian scholars as a dictionary of the national language in its complexity and unity. It contains a large number of slang and informal words. There is also a correspondence, where possible, between the regional (dialectal) and literary meanings of the words.

V. Dal was the first to use the term Толковый Словарь 'explanatory dictionary' in his Толковый Словарь Живого Великого Русского Языка (*Explanatory dictionary of the living great Russian language*), which was published in 1863 (Dal, 1863–1866). It was a pioneering dictionary that explained all the meanings of the words, its main purpose being to overcome the gap between written and spoken Russian. Accordingly, A. Shakhmatov gave a highly positive evaluation of this profound reference work.

As he was opposed to foreign borrowings in the Russian language, Dal registered various dialectal words alongside literary words in the dictionary, trying to show productive models of word formation based on народный 'folk language'. The dictionary contains 200 000 entry words, among them more than 80 000 that had never been included in dictionaries of the Russian language. In his effort to describe the living Russian language, he combined the alphabetic and thesaurus word orders, registering synonyms in the entries. This dictionary opened a new era in Russian academic lexicography.

Thus, in Russian lexicography of the 19th and early 20th centuries, there are three interconnected themes: dictionaries of the modern literary language, historical dictionaries, and dictionaries of regional dialects. Each of these themes had numerous branches that varied in purpose and range.

The Soviet Period

The Soviet period of Russian lexicography, which made use of the rich legacy of pre-revolutionary academic dictionaries, began with Словарь Русского Языка (*Dictionary of the Russian language*), compiled by a group of distinguished scholars and edited by D. Ushakov (Ushakov, 1935–1940). It was norm-based and registered many new words developed after the revolution, for example,

активист	activist	(a person active in social reform)
комсомолец	a member of the Komsomol	(Young Communist League)
многотиражка	published in large editions, e.g. factory newspaper	
рационализатор	rationalizer	
хлебозавод	large-scale bread-baking factory	
шефство	patronage	

and so on. Each word had a normative grammar and pronunciation label along with information on etymology, style, etc. Many collocations were included, which was a new feature of the dictionary. The selection of words was naturally based on Communist ideology and is the most vivid product of the ideologically colored reference works of the Soviet era.

Several other dictionaries of this kind appeared subsequently, the most popular being S. Ozhegov's dictionary, which went through more than 20 editions from 1949 on. But the most significant project undertaken by scholars in the 20th century was an enormous academic dictionary of the Russian language in 17 volumes that was published from 1948 to 1965, Словарь Современного Русского Языка (*Dictionary of the modern Russian language*). It contained many citations from classical Russian literature, fiction, and periodicals illustrating each word, with the etymology of the word being the central feature of each entry. The majority of definitions were ideologically oriented and influenced by Ushakov's dictionary.

The Perestroika Period

The latter part of the 20th century, beginning with perestroika, was marked by growing interest in borrowings from contemporary foreign languages, especially English, as well as in colloquial words and jargon, which was not previously recorded in dictionaries of the national language. At the same time, ideologically colored words characteristic of Communist times, such as:

агитпункт	propaganda/agitation centre
идейно-воспитательный	ideological and educational
партийно-хозяйственный	party-economic related, e.g. a meeting of party members and directors of factories to discuss local economy and development
партвзыскание	party penalty/fine
соцлагерь	a union of socialist nations, e.g. Bulgaria, Hungary, Poland and USSR
народный избранник	a person chosen by the people

began to disappear from the modern Russian language.

The process of borrowing into the Russian language is explained first and foremost by the prestige of the foreign language. For example,

презентация	presentation
представление	show (theatre/circus)
эксклюзивный	exclusive
консалтинг	consulting

New concepts also demanded new words:

автобан	motor way
блейзер	blazer/jacket
грант	grant
дайджест	digest
скоч	scotch (whisky reference)

The first dictionary of the Russian language at the end of the 20th century that had no predecessors was a new type of a national language dictionary (Sklyarevskaya, 1998). It included new concepts of the modern reality:

перестройка	perestroika
контрперестройка	against perestroika
пост перестроечный	post perestroika period
рынок	market
рыночник	a person in favour of market economy
дорыночный	before market economy
антирыночник	a person against principles of market economy

borrowings:

консенсус	consensus
приватизация	privatization
презентация	presentation
брифинг	breifing
менеджер	manager
маркетинг	marketing
рейтинг	rating
триллер	thriller
имидж	image
эксклюзивный	exclusive

slang/colloquial:

балдёж	wild, happy time
беспредел	chaos
лимон	million (money reference)
лажа	lies
вешать лапшу на уши	to lie
на халяву	to get something for nothing, for free
затрахать	to be sick and tired, bored (swear word)

jargon (mainly youthful):

общага общежитие	halls of residence (student reference)
стипуха стипендия	grant/scholarship usually paid monthly in Russian universities
шпора шпаргалка	notes used in an exam/test to cheat
удочка удовлетворительно	a satisfactory work (exam; c)
потрясно, классно, обалденно	great, fantastic, amazing (adv.)
убойный, клёвый	great, the best (adj.)
ржать	to laugh a lot, laugh out loud
кайф	happy, pleasant life/ experience
балдеть	to like something very much
прокол	failure in something
ишачить, пахать	work very hard without thinking or complaining/ to do donkey's work
заказать	to kill, do harm to

vocabulary of the criminal world:

шмон	search
баланда	2 meanings: Soup in prison, place full of people
вышка	capital punishment
стукач	'grass'
блатной	jailbird, old lag
мокрушник	murderer/killer
перо	knife

Terminology, especially from business and economics, is also recorded:

рублевое покрытие	money cover – to pay with roubles (Russian money)
ваучер	voucher
монетаризм	method of controlling economic process (e.g. inflation) by putting money into it
лизинг	lease (on a building, office)
экономическое информационное/ правовое пространство	co-operation of countries on the basis of agreement in areas of economy, information and law

political terms:

консенсус	consensus
стагнация общественной жизни	deterionation of life in a society

computer terms:

банк данных	database
интерфейс	interface
байт	byte
принтер	printer

sport:

фристайл	freestyle
бобслей	bobsleigh
ски-стрим	extreme sking
кикбоксинг	kick boxing
файтер	fighter

This dictionary became very popular, not only among Russian users but also among foreigners studying Russian. It was revised and republished in 2001. It certainly inspired modern Russian lexicographers to apply new productive approaches to the description of the modern Russian language in use.

The Proposed New Academy Dictionary

Discussion concerning the issue of the proposed Словарь Новой Академии (*A New Academy Dictionary*) (NAD) in 20 volumes has gained momentum since the early 1980s. NAD will have essential differences from all previous dictionaries of the Russian language. The main issues are: its treatment of the lexicographic object (the lexical system corresponds to the linguistic perceptions of contemporary native speakers); its orientation to current word usage; its comprehensive coverage (about 200 000 lexical units); and its lexicographical methods (including a computational lexicographer's workbench). NAD aims to describe the living, functioning language by using a wide range of lexical material resorting to a synchronous linguistic cut. Unlike previous academic dictionaries, this one rejects the traditional perception of the Russian language and will try to describe the living language without a historical perspective.

The notion of 'contemporaneity' has been changed to 'synchronism,' as the theoretical foundation for the dictionary. Synchronism is understood as one of the elements of the dynamic equilibrium of the language system. It is supported by the norms of the time period during which the dictionary is compiled. A synchronous type of dictionary contains only certain elements of the language system: neutral modern language elements that join the stable core of the lexical system, elements that have certain stylistic functions, certain obsolete words, and elements that are part of phraseology units.

The objectives of the dictionary caused a reconsideration of its empirical basis. According to the conception of NAD, its sources will consist of texts that reflect the language of contemporary native speakers. A multitude of derivatives along with new words make up the first source for the word list. Until now, these words have been excluded

from explanatory dictionaries. The second source for the word list is low-level colloquial vocabulary, which has been treated extremely cautiously in the past and seldom can be found in dictionaries. Borrowings are the third source for the word list. Word formation will serve as one of the most productive sources of new vocabulary. Another source of vocabulary is terminology. The scope and weight of technical terminology in the Russian language has not only increased but has become a menace. The last source of vocabulary for the New Academy Dictionary consists of word equivalents or *word combinations equal to a word, both formally and functionally.* Archaisms that are judged to be semantically and stylistically suitable for present-day usage will also be found in the macrostructure of the dictionary.

Enlargement of the word list in comparison with previous dictionaries will improve its main theoretical purpose—the elaboration of a segmentable, multiaspect, and differentiated system of functional and stylistic labels. Considerable enlargement of the word list, due to the inclusion of a number of new lexical elements, is not contrary to normative dictionary principles. The vocabulary will be differentiated according to its functional and stylistic features. Every lexical unit will be characterized and evaluated according to the norm. Moreover, characteristics of usage limits will be included in the dictionary.

NAD authors are making an attempt to structure all stylistic labels according to certain new parameters. These are: social and functional; chronological; territorial and social; normative; genre and stylistic; and connotative (expressive, emotive, evaluative). This stylistic label system was based on the one developed by V. Vinogradov for Толковый Словарь (*The Explanatory dictionary*) as edited by D. Ushakov.

The Relationship between Lexicography and Linguistic Theory

The theoretical basis of lexicography was explored much later than the first Russian dictionaries, in the middle of the 20th century by L. Scherba (Scherba, 1974). He developed three fundamental categories: typology of dictionaries, principles of semantic analysis for making a dictionary entry, and discovery of 'deeply' embedded semantic elements. His six oppositions describing the main types of dictionaries—academic/informative; encyclopedic/general; concordance/defining; ordinary/ideological; defining/translating; nonhistorical/historical—became the topic of numerous subsequent discussions.

As well as establishing the notion of language norms, Scherba defined stylistic criteria and promoted other ideas, such as comprehension of the lexical system as the vocabulary of a certain human community at a certain moment, and establishing two types of lexical relations (word-to-word relations and meaning-to-meaning relations within a single word). According to Scherba, the role of and knowledge within a dictionary is based on a complex of lexicological and lexicographic studies, on the one hand summarizing theoretical studies and on the other hand being a source and basis for further theoretical research.

The contribution of another well-known Russian linguist, V. Vinogradov, to the theory and practice of Russian lexicography includes many fundamental scientific studies and hundreds of articles (Bogatova, 1999: 253–278). His research was mainly based on critical analyses of Russian dictionaries. Thus, first and foremost, he discovered and formulated problems in the theory of lexicography and theoretical lexicology, his main contributions being a theory of meaning and working out of a phraseology theory. Vinogradov's fundamental statement about types of phraseological units became the starting point for the rapid and successful development of phraseology as an independent linguistic discipline with its own terminological system and object of study, with special reference to dictionary making.

Vinogradov created an integral semantic conception that determined the future of Russian semasiology (Vinogradov, 1977). The most important aspect of Vinogradov's semantic conception was determining the structure of lexical meaning. He interpreted the structure of lexical meaning as a complex interaction of semantics and grammar. Following Vinogradov, generations of Russian linguists understand lexical meaning as 'material matter formed according to the laws of grammar of the given language, an element in the general semantic system of the given vocabulary.' This overall definition of a word's lexical meaning was derived directly from lexicographical practice. It manifests itself in the continuous merging of one meaning of a word into another, in disputes about how many meanings a word has and in constant debates about the accuracy of definitions.

Vinogradov argued that lexical meanings related to reality and lexical meanings related to the lexical system are different. This observation led him to one of the most important conclusions for lexicology and semasiology: meanings are not homogeneous. There are qualitative differences in structures of various kinds of lexical meanings.

Vinogradov also developed a typology of lexical meanings. This typology outlines three main types of lexical meaning: free, phraseologically bound, and functionally and syntactically fixed. Structurally conditioned meanings represent an additional type. The typology offered by Vinogradov is still relevant today: it predicted the development of various

trends in semasiology: the theory of synonymy, homonymy, linguistic metaphor, and the theory of *nominalization*. It also contributed to the development of phraseology and lexicography.

The third semantic conception offered by Vinogradov was the issue of the semantic limits of a word. He saw this as a problem of homonymy in general and lexicography in particular. The issue concerning the modern Russian language had been under discussion for many years. Vinogradov introduced a number of proposals for determining the limits and norms of the modern Russian language. At first this question arose in connection with the need to determine the scope of an explanatory dictionary and as a matter of combining normative, stylistic, and historic principles in one reference book. Drawing on the ideas of Scherba, Vinogradov considered the understanding of structure, volume, contents, limits, and norms of the modern Russian language to be correlated within narrow chronological limits.

Further attempts to reflect the common literary language, codified and represented mainly by fiction, were undertaken in explanatory dictionaries of the modern Russian language. In the 1950s and 1960s, Russian lexicographers turned directly to the analysis of a dictionary's objectives (Sorokaletov, 1998). These objectives are: objectives of explanatory lexicography; structure and principles of making a dictionary entry; issues of homonymy and word identity; role of terminology in the national language; *substantiation of information capacity* as determined by the type of dictionary; criteria of synonymy; and stylistic diversity of the language. Multi-aspect and multilevel theories of typologies of lexical meanings are currently being developed on the basis of Vinogradov's ideas.

The search for systematic and unified principles of lexicography led to the formation of an integral systematic conception of vocabulary and stimulated semantic research. The systematic description of the vocabulary in the dictionary introduced by J. Apresjan (Apresjan, 2000) presupposes the following factors: discovery and description of external connections and relations of a word with other words; description of semantic structure of a word; and analysis of the seme structure of each lexical and semantic variant necessary for writing a definition. The conception of lexical and semantic systems has been accepted in modern Russian linguistics as an organization of the word stock with all its elements naturally tied together, interacting and correlating with each other in paradigmatic, syntagmatic, and derivative relations. Moreover the system possesses a dynamic character, and the system itself is interpreted as a model of a linguistic picture of the world.

The degree of vocabulary ordering within the system (and in the mind of a native speaker) is viewed by Russian linguists in two different ways. According to the idea of J. Karaulov, the system is completely ordered, and all of its elements are bound together into one solid unity (Karaulov, 1981). None of the elements can be separated. P. Denisov, on the other hand, argued that the system is relatively ordered. Some zones can have more or less unity, while others can be isolated. Variants on this issue are described as different levels of analysis (Denisov, 1974).

External and internal aspects of the lexical and grammatical system presuppose two kinds of vocabulary description in a dictionary. Research into the external aspect is aimed at revealing the synonymic, hyponymic, and other relations between words, as well as studying different kinds of lexical groups and formations. Traditional interpretations of the internal aspect are connected with studying lexical and grammatical variant correlations within one lexeme (polysemy) (Scherba, 1974; Karaulov, 1981). There are no contradictions between the external and internal aspects of the system; they simply show different stages of analysis. The method of componential analysis offers an insight into every lexical and semantic item. Thus, indivisible semantic unities become segmentable. These discoveries reveal three aspects of the lexical and semantic system: external, internal, and deeply embedded. This corresponds to the three levels of semantic analysis.

Semasiology was developed in the 1980s and covers various aspects of a word's semantic structure: from the simple correlation of a word and a concept, to the theory of reference, to a description of a hierarchically organized structure of lexical meaning. Critical analysis of dictionaries revealed the imperfection of the information presented in them. A new level of structural comprehension as well as lexical meaning led to the formation of a new trend in semasiology – the study of expression. Combining the expressive components of a word with its semantics became the object of this trend.

The idea of deriving lexical meaning from a group of words and text analysis became linguistically fruitful, going beyond mere lexicographic tasks and contributing to important theoretical conclusions. The analysis leads to the conclusion that the main unit of a dictionary – the dictionary entry – is a cluster of linguistic knowledge concentrating all information about a word. This conclusion makes it possible to use the structure and contents of a dictionary entry as a basis for further scientific research.

New integral conceptions developed on the basis of dictionary compilation and analysis of reference books include the conception of lexical compatibility,

language norms, the theory of synonymy, and the theory of reference. Linguistic pragmatics thus was generated as a lexicological discipline. It studies pragmatic information, not on the level of an utterance but on the level of a word. Stylistics was developed, along with semasiology. Stylistic research either was aimed at lexicographic needs or provided materials and ideas on dictionary issues for theoretical stylistics.

I. Mel'čuk carried out a series of linguistic studies of Russian in four domains of linguistic research: semantics and lexicography; syntax; phraseology; and morphology. These topics are grouped into seven thematic divisions, with special reference to basic problems of semantics and lexicography and the project of a new type of monolingual theory-oriented, semantically based collocational lexicon: the explanatory combinatorial dictionary (ECD) (Mel'čuk *et al.*, 1984).

ECD is intended to be one of the central components of the natural-language meaning ↔ text model (*see* **Mel'uk, Igor Aleksandrovic (b.1932)**).

$$\text{meaning} \leftrightarrow \text{text} \begin{cases} \text{model} \\ \text{theory} \end{cases}$$

It contains full-fledged illustrations of two complete lexical entries; a thorough description within a lexicographic approach of all the senses of two Russian temporal adverbs and emotion verbs; a countability/noncountability feature related to the division of senses in polysemous nouns; the border zone between syntax, semantics and lexicography, and more.

Thus, the new model of ECD is an essential component of linguistic description within the meaning ↔ text theory, which describes a natural language as a kind of logical device, called the 'meaning ↔ text model of natural language.' The lexical entries of an ECD are designed to both test and demonstrate the apparatus devised for the description of any type of lexical unit within the framework of the meaning ↔ text approach. This instrument for lexical description claims to do justice to words both as paradigmatic units in the network of relations in the lexicon and as syntagmatic units systematically related to other similar units in a discourse.

The ECD follows certain promising trends present in contemporary lexicography. Three of them stand out: developing active types of dictionaries; emphasizing the universal character of monolingual dictionaries; and matching linguistic to encyclopedic information.

For a long time, the most common type of monolingual Russian dictionary was the comprehensive one, to which the user would refer in order to find out about an unfamiliar word or phrase found in a text. Such dictionaries were oriented towards making texts comprehensible, i.e., providing for the transition from a text to the meaning expressed by it. Using the traditional contrast between passive grammar (text understanding, or analysis) and active grammar (text production, or synthesis) introduced by L. Scherba more than 50 years ago, one could call these dictionaries 'passive.'

Several attempts to create dictionaries that satisfied the needs of foreign-language teaching were made in the 1930s. A new type of reference book was developed, aimed at users' practical needs and contributing to their production of texts in a foreign language. Clearly, the meaning ↔ text model and its indispensable component, the ECD, also aim at achieving this objective. In this sense, the ECD is an 'active dictionary.' It differs, however, from other active dictionaries in that the linguistic means needed for the expression of a given idea are selected for inclusion in the ECD according to explicitly formulated uniform principles, which are given a formalized description in special artificial languages (such as the lexical functions employed for the description of restricted lexical co-occurrence).

At the same time, the fact that expressions of a natural language in the ECD are explicitly associated with corresponding expressions of a 'deeper' formal language opens up the possibility of using the ECD not only in an active but also in a passive role, i.e., not only for the production but also for the understanding of texts. Thus, the ECD is potentially a reversible dictionary of a universal character, based on an integrated linguistic theory, and combining an explanatory dictionary with phraseological, derivational, and conceptual dictionaries, along with dictionaries of synonyms and antonyms and of syntactic patterns.

Until recently, traditional lexicography differentiated between two types of dictionaries: (1) linguistic dictionaries, which describe meanings of words from the viewpoint of an unsophisticated native speaker, and (2) encyclopedic dictionaries, which describe the corresponding objects, processes, facts, and so forth. However, the development of linguistics, semiotics, and other related sciences has led to the idea that the correct use of words is determined to a significant degree by the way a language breaks down in reality into distinct fragments and by what typical linguistic representations are used to express these fragments.

Consequently 'explanatory' dictionaries (Тол ковый Словарь) began to provide minimal encyclopedic information for words with a strong cultural and factual-knowledge background. Following this trend, the ECD includes elements of encyclopedic information in linguistic dictionary entries. However, unlike other dictionaries, it strictly distinguishes

between these two types of information, presenting them in different sections of the dictionary entry. In maintaining this basic division between linguistic information and encyclopedic material, the ECD is more consistent with traditional lexicography. At the same time, the ECD possesses two important features that distinguish it from most existing dictionaries: its theoretical orientation and its formal character.

The ECD is completely theory-oriented. As stated above, it is conceived and implemented within the meaning ↔ text theory, and the lexicographic method used is intimately tied to this general linguistic framework. The ECD does not aim to satisfy the specific needs of a well-defined class of prospective users; nor does it take into account their probable level of understanding of the corresponding language. It is designed primarily for scientific purposes and tries to bridge the chasm between lexicography and theoretical linguistics by laying the basis for a fruitful interaction between both fields—an interaction that heretofore has been minimal.

In accordance with its main goal, the ECD is explicit and systematic, which means that it never relies on informal methods of communicating information about words or on the native speaker's intuitive knowledge of his language. The ECD also employs circular definitions and requires similar descriptions for semantically similar items. Thus, for example, all names of institutions or all names of movements must be described in exactly the same manner; all differences in the wording of the definitions or in the presentation of lexical collocations of semantically related words must be justified by actual linguistic differences.

The ECD is a monolingual dictionary with the following important features: it is an active, general-purpose dictionary with a substantial element of encyclopedic information; it is based on a modern linguistic theory, strongly emphasizing systematic, explicit, and formalized presentation of all information in the microstructure. The basic unit of an Explanatory Combinatorial Dictionary is a dictionary entry corresponding to a single lexeme or a single phraseme, i.e., one word or one set phrase taken in one particular sense. A family of dictionary entries for lexemes that are sufficiently close in meaning and share the same signifier (i.e., have an identical stem) is subsumed under each main entry.

The structure of a dictionary entry consists of such main sections as morphological information (gender of nouns, aspect of verbs); stylistic specification or usage label (specialized, official, colloquial, poetic); definition (elementary and complex word senses of the language in question); illustrations; lexical functions (synonym, antonym, diminutive, conversive, etc.); examples; encyclopedic information; idioms. The ECD is likely to become a central component of automatic text synthesis and analysis systems because it presents all essential information about the vocabulary of the language in question in an explicit and systematic way.

The ECD represents a contribution to language theory, at least insofar as it provides for the development and refinement of a semantic metalanguage, the systematic account of phraseology, and the development of a multifaceted approach to the word taken as the sum of all its semantic and syntactic characteristics. Various advantages are provided by the ECD in the area of language instruction, as well as in any activity connected with the development of language skills. Textbooks, pedagogically oriented dictionaries, reference works, and so on can be successfully developed along the lines of the ECD.

The Present Day: New Dictionary Types

Dictionaries for General Purposes

A new group of lexicographers from St. Petersburg integrated the experience of modern linguistic theory into lexicographic practice, borrowed the rich practical experience of British publishers such as Harper Collins, and created a new series of reference works of different sizes (Concise, Pocket and Gem). Their main product, Словарь Русского Языка (*Dictionary of the Russian language*), edited by D. Dmitriev, is an example of a dictionary of the new generation (Dmitriev, 2003). It represents a new type of dictionary intended to answer the question, 'How can one speak Russian effectively?'

Its compilers borrowed the policies of The Collins Cobuild dictionaries and apply their typical features: the dictionaries are corpus-based; full sentences are used to define words; headwords and the alphabet are marked with colors; words are exemplified in real contexts and collocations.

The dictionary is object-oriented. Every meaning is based on ideas about objects of reality, which possess different properties (they may be participants in communication, may act in different situations, etc.). Objects may be physical or abstract. Thus all objects are divided into classes, for example, living organisms, transportation vehicles, and so on. Every object is connected in our mind with a certain class, and in the language they have certain lexical meanings.

Thus the key to word usage in this dictionary is understanding that groupings of typical word usage that refer to different classes of objects have different collocational models, differ in form, and acquire definition in context. All of these features help the user to

understand the living Russian language and make this an active type of dictionary.

Special Purposes Dictionaries

Parallel to Russian academic lexicography, various groups of special dictionaries were developed. On the one hand, these adopted practices from academic dictionaries, but on the other hand they had their own peculiar features of macro- and microstructure. These include dictionaries of slang, difficult words, new words, and archaisms; phraseological, dialectal, etymological dictionaries, and so on. Among these, author and LSP dictionaries have the greatest share and are worth describing.

Single-Author Dictionaries Author dictionaries have a long tradition in Russian lexicography, going back to 1883, when the first glossary devoted to the words used by a single Russian writer, Derzhavin, compiled by academician J. Grot, was published. This was an alphabetically arranged word list with over 1750 headwords, accompanied by one or two illustrations, without part of speech labels or definitions, and including an index of proper names. Among these were proper names of mythological origin (*Dazhbog*, *Lada*, *Lel*), folklore characters, and ancient names (*Afet'* 'Europe', *Bel't* 'the Baltic sea').

The appendix of proper names gives exhaustive information about various historical, biographical, geographical, political, and biblical names in Derzhavin's works. Each entry has been supplemented by Grot's comments and references to Derzhavin's fiction, letters, or documents. Thus, the lexicographer introduced two types of author dictionaries: a concordance to Derzhavin's poems and a complete alphabetical index of the proper names used (see Karaulov, 2003: 17).

This dictionary was followed by modest attempts to describe the vocabularies of other famous Russian men of letters. A dictionary of the works and translations of D. Fon-Vizin appeared in 1904, compiled by K. Petrov. This was the first attempt to create a general-purpose lexicon for all genres of a writer's literary works. In spite of the fact that this new dictionary had a number of faults (the most significant one being an absence of definitions in many entries), its development is considered to be a major development in the lexicographic description of an author's vocabulary.

The language and style of A. S. Griboyedov's comedy 'Woe from Wit' by V. Kunitzky was published in Kiev in 1894, followed by *Materials for a dictionary of Pushkin's Prose* by V. Vodarsky. This was devoted to fiction and historical and critical prose only, and although it does not contain systematic definitions, the senses are differentiated as in regular concordances (Karaulov, 2003: 37).

The second period of Russian author lexicography is notable for *A Schedrin dictionary* by M. Olminsky. This was compiled in the late 19th century but only published in 1937. The majority of entries are proper names (the names of characters, with references to the works in which they appear), ideologically important words and word combinations, typical images, and cliches, which reveal Schedrin's artistic conception. The entries contain quotations showing the ideological importance of the characters or sarcastic or ironic implications. Despite the fact that both of the above-mentioned editions are not linguistic in the traditional sense of the term, their place in the general typology of single-author dictionaries is quite significant.

The major event of the second period of Russian single-author lexicography was the academic dictionary of A. Pushkin's complete works (*Pushkin dictionary*, 1956–1961). Pushkin, of course, significantly contributed to the formation of Russian literary language. This project had originated earlier in the century, but the first volume of the dictionary was published only in 1956, the volume's main purpose being a description of the Russian vocabulary in Pushkin's time. It contains detailed entries with grammar labels, full definitions of meanings, and illustrations of words as used by Pushkin. Being a historical dictionary, it was greatly influenced by Russian academic lexicography and does not show particular stylistic features of the writer's language. Instead, it uses Pushkin's works to explain and illustrate the Russian language in the early 19th century.

Another project describing the language of a single author was launched at Leningrad University in the 1950s (Словарь Автобиографической Трилогии М. Горького (*A dictionary of autobiographical trilogy of M. Gorky*), 1974–1990). B. Larin, the originator of the theory of single author lexicography, conceived the idea of a complete explanatory dictionary of M. Gorky's autobiographical trilogy. This was a new type of stylistic author dictionary, and its purpose was to show the individual peculiarities of a writer's language. The compilers worked out a range of stylistic labels that were later borrowed by compilers of other single-author dictionaries, such as one dealing with Gorky's dramatic language (Словарь Драматургии М. Горького (*A dictionary of the dramaturgy of M. Gorky's plays*), 1994).

Both dictionaries opened up a new era in Russian single-author lexicography, (see Karaulov, 2001), notable for explanatory lexicons (or Толковый Словарь), and a significant group of indices based on

frequencies of words in the works of M. Tsvetaeva, I. Brodsky, and other Russian poets.

The beginning of the millennium was marked by a two-volume work called Словарь Русской Поэзии 20 Века (*Dictionary of Russian poetry of the 20th century*) (2001–2003), which contains entries from all the major Russian poets of the 20th century, with a complete description of the usage in their texts, accompanied by stylistic and expressive labels and illustrations. This is a completely new type of historical-stylistic dictionary, which combines concordance with lexicon and aims to describe the language of the poets' period as well as their individual peculiarities.

Dictionaries of Language for Special Purpose (LSP)
LSP dictionaries were originally classified in Russian lexicography as терминологический 'terminological' or науино-технический 'scientific-technical terms'. They appeared in the early 1930s with the effective development of Russian science and technology, which demanded mono- and bilingual dictionaries describing different subject areas, such as metallurgy, energy, chemistry, physics, etc. (Marchuk, 1992). Since then, a Russian terminological school has been established and hundreds of linguistic and encyclopedic LSP reference works of different types and sizes have been published.

The most successful attempt to describe the historical and typological picture of Russian LSP dictionaries was made by Alexander Gerd (Gerd, 1985). According to his main idea, all LSP dictionaries must be based on a logico-notional scheme of a particular subject field, accompanied by specialist expertise. His idea found its development in numerous theoretical works and dictionary projects.

Nowadays, LSP in Russia has at its disposal monolingual, bilingual, and multilingual dictionaries of many different types (Leitchik, 1999). Modern LSP lexicography in Russia is greatly affected by computers, so many dictionaries have recently appeared on the Internet.

Culture-Oriented Dictionaries

The culture of speech has recently become a promising field of lexicographic research in Russia. The culture of speech embraces both language and rhetorical proficiency and is understood by most Russian scholars as the ability to chose the linguistic means that are proper and sufficient for achieving a communicative purpose. The culture of speech thus presupposes language acquisition (studying its grammatical, lexical, and phonological features) and learning the ethics of verbal interaction and the regulation of effective speech behavior, i.e., the conditions, principles, rules, and means of the appropriate and expressive arrangement of written and oral texts.

Creative use of the various linguistic means available is based on profound knowledge of language, which is, in its turn, the main goal of modern education. It is obvious, considering its educative goal, that the research by Russian scholars in the field of the culture of speech would inevitably result in an encyclopedic volume aimed at explaining the culture of the modern Russian language in all its many aspects.

The encyclopedic dictionary Культура Русской Речи (*The culture of Russian speech*), published in 2003, became the first reference book to define the subject field, as previously no attempts had been made to give a clear and precise description (Ivanov, 2003). The work started in 1989, when the main decisions about the dictionary were made. They can be summed up as follows:

- to avoid an excessive word list, it was decided not to focus on the historical perspective but instead to give a broad coverage of modern terminology with some etymological data;
- the editors did not include the terms of grammar, stylistics, poetry studies, or semiotics because of the variety of available specialized dictionaries in those subject fields;
- some subject field terms that have little connection with philology were included as headwords, such as лингвистическая экспертиза 'linguistic expertise'; нейролингвистическое программирование 'neurolinguistic programming'; реклама 'advertising';
- some entries on the theory of communication were deliberately targeted at specialists aware of the subject's peculiarities, not at nonprofessional users, such as адресант 'addresser', адресат 'addressee', каналы речевого воздействия 'channels of speech influence';
- while defining words that have explanations supplementing each other, the editors sometimes place two definitions by different scholars together, even if they seem to be incompatible, for example, лингвистическая экология 'linguistic ecology', стилистика 'stylistics';
- up-to-date 21st century mass-media texts were chosen as the main source of illustrative examples, although some examples come from the 1990s.

The structure of the dictionary is arranged in five parts:

1. general terms of the culture of speech, rhetoric studies, stylistics, and adjacent subject fields;
2. functional styles, genres, stylistic resources of the language;

3. rhetoric methods and stylistic devices;
4. mistakes and faults of speech;
5. reference works.

The dictionary is easy to use, as it has an alphabetical arrangement. The headwords are given mostly in the singular. In cases where the headword is a combination of a noun and an adjective, the variant starts from the adjective if the word combination is a unified term. When a group of terms is united by a general term, the entry starts from the latter; the same holds true in the case of synonyms: the entry starts from the most frequent. In the back matter, there is a list of the entries, which makes searching easier.

It is worth mentioning that the dictionary allows one to solve various tasks. In case the purpose is researching correct and effective speech production or using stylistic devices, the editors advise that users should first study the contents of the second and the third parts, then consult the entries. If the purpose is editing texts or correcting mistakes, the contents of the fourth and the fifth parts will be of greater help. The dictionary can also serve a perfect tool for college and university students reading for examinations in the culture of speech, stylistics, and rhetoric studies.

Rwanda: Language Situation

J Rusanganwa, National University of Rwanda, Butare, Rwanda

© 2006 Elsevier Ltd. All rights reserved.

Rwanda is a country in eastern Africa bordered by the Democratic Republic of Congo, Burundi, Uganda, and Tanzania. It has about 8 million inhabitants.

Four main languages are spoken in Rwanda, each with their own status. Kinyarwanda is a national and official language and plays an important role in coordinating the political and social interactions among Rwandan returnees from various English- or French-speaking countries of refuge. French and English are used as official languages and for communication in academic matters. Some Rwandan families, especially well educated ones, even use English or French in their household communication. Kiswahili, though widely spoken, has not yet attained an official position; it is considered the commercial language used among indigenous and Afro-Asian traders. However, Kiswahili is taught as a subject in some secondary schools and used by Muslims as a language of communication in religious matters.

Kinyarwanda is spoken in the Republic of Rwanda as well as in neighboring countries such as the Democratic Republic of Congo, Burundi, Uganda, and Tanzania. Gasarabwe (1992) estimates that Kinyarwanda is spoken and understood by more than 20 million people. This number includes 8 320 000 Rwandans in Rwanda (according to the 2002 national census) and more than 5 million speakers in the neighboring countries and in the diaspora. In addition, Kinyarwanda is mutually intelligible with Kirundi, the language of about 7 million Burundians.

Kinyarwanda is a language of the Benue-Congo branch of the Niger-Congo family and belongs to the Bantu group, spoken in the central, eastern, and southern parts of Africa. Kinyarwanda has been classified by Guthrie (1948) as D 61, belonging to group D 60. However, following work by Meeussen (1967) and Schoenbrunn (1994), Kinyarwanda has been classified as belonging to the interlacustrine zone J, and, within this zone, as J 61, together with Giha and Kirundi. There are a number of slightly distinct alternative names for Kinyarwanda, all revolving around round the stem *-rwanda-,* e.g., Runyarwanda, Ikinyarwanda, Rwanda, Orunyarwanda, Urunyarwanda, etc. The name of their language for Rwandans themselves is Ikinyarwanda. According to available research (e.g, Nkusi, 1986: 289), Kinyarwanda has about a dozen dialects. These include Ikireera, Ikigoyi, Igisoozo, Ikinyanduga (standard Kinyarwanda), Igikiga (ubulimi), Igishobyo, Oluciga, Igihavu, Ururashi, Amashi, and Ikiyaaka.

The writing system of Kinyarwanda employs Latin characters, since the first writers of this language were missionaries who wrote the prayer book *Le livre de priere / Igitabo cy'abakristu bo mu Rwanda* in 1907, a manuscript produced in Maison Carée France.

Some sounds of Kinyarwanda are not found in IPA, so some linguists (e.g., Gerla, 1980; Kimenyi, 1983; Jouannet, 1984) have devised new phonetic symbols to represent these sounds, e.g., for the clusters *shy, jy, mf, pf, ts, mpky.* Kinyarwanda, as most other Bantu languages, is a tone language. Two tones are distinguished by the diacritics high (/) and low (\) to characterize the rising and falling tones respectively, e.g. *umuhùngu,* 'boy' and *abâna,* 'children.'

As any other language, Kinyarwanda can be used not only in communication but also in specialized domains, including drama, poetry, and other technical domains for which specialized Kinyarwanda is needed. Unfortunately, Kinyarwanda has not yet been used as a medium of instruction in schools except in the lower primary cycle. It is only taught as a subject from upper primary school cycle through secondary school and to university levels, as secondary schools and universities in Rwanda use education materials written in English or French. For this reason the policy of bilingualism was adopted in 1996, making both English and French used as mediums of instruction. It is still debatable (Nkusi, 1980) whether Kinyarwanda will become an instrument of modern or technical communication. If asked their points of views, many Rwandans would argue that this would not be a simple matter, since most of the modern communication and technology is imported from abroad. However, Kinyarwanda adopts to this modernity and assimilates it by finding equivalent terms. Only the technology invented by Rwandans is directly named in Kinyarwanda.

The writing system of Kinyarwanda employs Latin characters, since the first writers of this language were missionaries who wrote the prayer book *Le livre de priere / Igitabo cy'abakristu bo mu Rwanda* in 1907, a manuscript produced in Maison Carée France.

Some sounds of Kinyarwanda are not found in IPA, so some linguists (e.g., Gerla, 1980; Kimenyi, 1983; Jouannet, 1984) have devised new phonetic symbols to represent these sounds, e.g., for the clusters *shy, jy, mf, pf, ts, mpky.* Kinyarwanda, as most other Bantu languages, is a tone language. Two tones are distinguished by the diacritics high (/) and low (\) to characterize the rising and falling tones respectively, e.g. *umuhùngu,* 'boy' and *abâna,* 'children.'

As any other language, Kinyarwanda can be used not only in communication but also in specialized domains, including drama, poetry, and other technical domains for which specialized Kinyarwanda is needed. Unfortunately, Kinyarwanda has not yet been used as a medium of instruction in schools except in the lower primary cycle. It is only taught as a subject from upper primary school cycle through secondary school and to university levels, as secondary schools and universities in Rwanda use education materials written in English or French. For this reason the policy of bilingualism was adopted in 1996, making both English and French used as mediums of instruction. It is still debatable (Nkusi, 1980) whether Kinyarwanda will become an instrument of modern or technical communication. If asked their points of views, many Rwandans would argue that this would not be a simple matter, since most of the modern communication and technology is imported from abroad. However, Kinyarwanda adopts to this modernity and assimilates it by finding equivalent terms. Only the technology invented by Rwandans is directly named in Kinyarwanda.

Though not an international language, Kinyarwanda is widely spoken in the world. Apart from being spoken in the central and eastern parts of Africa, it is also broadcast over BBC, VOA, and Deutsche Welle. These emissions are intended to solve political and economic problems in Africa's Great Lakes region and in particular for Rwanda, which experienced terrible genocide in 1994.

Ryukyuan

M Shibatani, Rice University, Houston, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

Also known as Luchuan and Okinawan, the Ryukyuan (Okinawan, Central) language comprises a group of diverse dialects of the former Ryukyu Kingdom, 1429–1879, which has lost much of its political and economic independence since 1609, when it fell to the hands of the Shimazu clan of Kagoshima, Kyushu. Following the Japanese annexation in 1879, the Ryukyu Islands became a prefecture of Japan – *Okinawa ken* 'Okinawa Pref.' – the status it regained in 1972, when the islands were returned to Japan from the American occupation. The Japanese government policy of fostering the use of standard Japanese since the time of the Meiji restoration (1868) has helped marginalize local dialects throughout Japan, and it has also had a pronounced effect in Okinawa. Based on the most recent census (2002), it can be estimated that of the current population of 1.3 million Okinawans, less than 300 000 people over the age 50 speak some variety of the Ryukyuan language with varying degrees of proficiency. Since children no longer learn to speak Ryukyuan, the language is bound to become extinct within the next 50 years unless active revitalization efforts are mounted.

Hypothesizing the sister-language relationship, Chamberlain (1895) remarked that the relationship between Ryukyuan and Japanese is something like that between Spanish and Italian or that between French and Italian. But unlike these Romance languages, the Ryukyuan dialects are often mutually completely unintelligible among their speakers, let alone to the speakers of any mainland dialect. Japanese dialectologists, on the other hand, have generally regarded Ryukyuan as a branch of Japanese dialects comprising three large groups: the Amami-Okinawa group (Amami dialect, Okinawan dialect), the Miyako-Yaeyama group (Miyako dialect, Yaeyama dialect), and the southernmost Yonaguni dialect group. The dialect of Shuri, the former capital of the Ryukyuan Kingdom, of the main Okinawa Island is generally regarded as the standard Ryukyuan, and it has served as a lingua franca of the Ryukyus.

It is generally estimated that the Ryukyuan stock split from the mainstream Japanese language at the latest around the 6th century A.D. (Hattori, 1976). Ryukyuan dialects show systematic sound correspondences with the modern Tokyo dialect, and they preserve a number of distinct features of Old Japanese. As shown in Tokyo–Shuri correspondences such as *ame:ami* 'rain', *hone:funi* 'bone', and *kokoro:kukuru* 'heart', the mid vowels have been raised in Ryukyuan dialects with the result of the standard five vowels *i, e, u, o, a* being reduced to the three vowels *i, a, u*. Innovative phonological developments include palatalization of /k/ before the /i/ corresponding to the Tokyo /i/ (Shuri *tʃiri* : Tokyo *kiri* 'fog'), centralization of the original /i/ in certain dialects (e.g., Miyako, Yaeyama), and the development of long mid vowels /o:/ and /e:/ from *au*, *ao*, and *ou*, as well as *e:* from *ai* and *ae*, respectively.

The features of Old Japanese preserved in Ryukyuan dialects cover all aspects of grammar. The Old Japanese consonant /p/ is preserved in such words as *piru* 'day time', *pi:* 'fire', and *pa:* 'leaf', corresponding to the Tokyo forms *hiru, hi,* and *ha*, respectively. The Ryukyuan lexicon contains older forms such as *tudzi* 'wife', *wan* 'I', and *warabi* 'child'. The notable syntactic features of Old Japanese preserved include the distinction between the conclusive form and the attributive form of verbs and adjectives; e.g., *katʃun* 'write-Conclusive' and *katʃuru* 'write-Attributive' correspond to the Tokyo form *kaku* used in both conclusive and attributive functions. Also seen is the preservation of the nominative function of the particle *nu* (Old Japanese/Modern Japanese *no*) in the main clause. In the total picture of the Japanese dialects, the Ryukyuan dialects form the most peripheral groups that preserve historically residual forms in line with the classical theory dialectology.

S

Saadya Gaon (882–942)

A Gianto, Pontifical Biblical Institute, Rome, Italy

© 2006 Elsevier Ltd. All rights reserved.

Saadya was born in Pithom (Abu Suweir) in the Fayyum district of Egypt, in 882. The name Saadya is an artificial Hebrew equivalent of his Arabic name Sa'id. He left Egypt in 905 and lived in Palestine but moved further and finally settled in Babylonia. There he was associated with the rabbinic Academy of Sura and became its head, hence the title Gaon, from 928 to 930 and again from 936 until his death in 942.

Between the two terms of his gaonate, he lived in Baghdad and wrote his famous *Kitāb al-Amanāt wa-al-I'tiqādat* ('The book of beliefs and opinions') in 933, which was later translated into Hebrew by the Ibn Tibbon family. In this book, Saadya attempted to reconcile Judaism with the philosophical thinking of Aristotle and Plato, his goal being to bring assimilated Jews back to Torah and its practical application. Saadya accepted the notion that reason was a legitimate standard for truth and set out to demonstrate that the Torah was compatible with reason. What was more, Saadya contended, the Torah was the finest source of truth available, and the study of Torah further developed one's rational judgment. Saadya translated into Arabic almost every book in the Hebrew bible, adding an Arabic commentary, although there was no citation from the books of Chronicles. The translation of the Pentateuch was contained in the Polyglot bibles of Constantinople (1546), Paris (1645), and London (1657), and in an edition for the Jews of Yemen.

In 913, he completed his first great work, the Hebrew dictionary to which he gave the title of *Sefer ha-Agron*. It had two parts, each arranged according to the alphabetic order of initials and of final letters respectively. Its purpose was to help writers find rhyming words. In a later edition, Saadya added the Arabic translation of each word, and also included passages concerning various memorable subjects about poets and their diction, naming the work in its new form *Kitāb al-Shi'r*. Then in his *Kutub al-Lughah*, he sought to explain the *i'rab*, or derivational and inflectional morphology. His *Tafsīr al-Sabʿīna Lafẓah* was a list of 90 Hebrew words, and some Aramaic, which occur only once or very rarely in the bible and explained from the vocabulary of the Mishnaic Hebrew.

Saadya laid the foundation of Hebrew grammar by establishing categories and rules. His dictionary, primitive and merely practical as it was, became the foundation of Hebrew lexicography. The categories of rhetoric, as they were found among the Arabs, were first applied by Saadya to biblical stylistic analysis. He was likewise one of the founders of comparative philology, through his explanation of the Hebrew vocabulary by their Arabic cognates.

Saami

P Sammallahti, University of Oulu, Oulu, Finland

© 2006 Elsevier Ltd. All rights reserved.

Saami is a subfamily of closely related languages within the Uralic phylum. At present, the Saami languages are spoken in an area arching from Dalecarlia in central Sweden to the tip of the Kola peninsula in northwestern Russia. The number of native speakers is ca. 30 000; ca. 85% of these speak North Saami (Saami, Northern) in Finland, Norway, and Sweden. The rest are unevenly distributed between Lule Saami (Saami, Lule) (south of North Saami in Norway and Sweden, estimated 2000 speakers), Kildin Saami (Saami, Kildin) (inland and northern coast of the Kola peninsula, 900 speakers), South Saami (Saami, Southern) (in the southernmost Saami areas in Norway and Sweden, 500 speakers), Skolt Saami (Saami, Skolt) (in Finland and some speakers in Russia, 400 speakers), Inari Saami (Saami, Inari) (in Finland, 300 speakers). The rest, Ume Saami (Saami, Ume) and Pite Saami (Saami, Pite) in Sweden between South Saami and Lule Saami areas, and Ter Saami (Saami, Ter) in eastern Kola peninsula are maintained by a score of old speakers each; Akkala Saami (Saami, Akkala) in southwestern Kola peninsula is probably extinct; the documentation of the minor languages is unsatisfactory (Ter, Pite, Ume) or highly unsatisfactory (Akkala).

There have been Saami idioms down to southern Finland and southern Karelia in Russia; of these idioms, the northernmost ones went into oblivion in the 19th century. There is evidence (language documents, etc.) of Saami presence south of the South Saami area in Sweden and Norway. Loanwords from Finnic, Proto-Indo-European, Aryan, Germanic, Baltic, and Slavic witness contacts with other linguistic groups. There is an ostensible non-Uralic substrate, especially in place names.

First Saami books date to 1619. The author belonged to a trader family and the language represents a pidgin with Saami, Finnish, and Swedish words and hardly any inflection. The first books representing Saami vernaculars (Lule Saami, Ume Saami) were published in the same century. At present, six Saami languages (South, Lule, North, Inari, Skolt, and Kildin) have a literary norm.

The Saami languages are structurally close to the rest of the Uralic languages. The finite verb agrees with the subject and is conjugated in three numbers (singular, dual, and plural), three persons (first, second, and third), and two tenses (the present/future and the preterit) in most languages; the auxiliary *leat* 'to be' together with nonfinite forms of the main verb is used to form aspectual compound forms (progressive vs. terminative aspect in both tenses, e.g., *lean boahtime* 'I am coming' vs. *lean boahtán* 'I have come'). The number of morphological moods varies from two (indicative, imperative) to five (indicative, conditional, potential, imperative, adhortative).

Negation is expressed by a negative verb; in the idioms southwest of North Saami, it has two tenses. In North Saami and east of the language area, tense is encoded in the nonfinite main verb (e.g., North Saami *in mana* 'I do not go' vs. *in mannan* 'I did not go'). The rest of the auxiliaries (mostly for epistemic and deontic modalities) show a more complete conjugation. In addition to compound tenses the nonfinite verb forms are also used for sentence-embedding, e.g., *Máret logai Máhte* [AccSg] *boahtán* [Perfect Participial] 'Mary said that Matthew has come.' Derivation is extensive within and across word classes; in verbs, there are several morphological passives and causatives in addition to a wide selection of aspectual derivatives (frequentative, subitive, etc.).

The Saami languages are nominative-accusative languages; in North Saami, some verbs denoting natural processes may take their single participant argument either in the nominative or in the accusative (e.g., *biegga* [NomSg] *garai* 'the wind became harder' ~ *garai biekka* [AccSg] id.). The basic word order in most Saami idioms is SVO but the older SOV is still dominant in South Saami, and the object neutrally precedes its nonfinite head (S Aux O V). Word order is free for the dependents of the verb and determined by pragmatic factors; the attribute precedes its head; postpositions dominate over prepositions.

In addition to the grammatical cases nominative (= no case) and accusative, nominals have the local cases illative, inessive, and elative (illative and locative in North Saami and the languages east of its area), the predicative cases comitative, essive, and abessive; as a rare case of 'degrammaticalization,' the abessive ending has evolved into a postposition in North Saami (e.g., **guolihaga > guoli haga* 'without fish'). The local cases are also used in nonlocal arguments (e.g., *Máhtte ballá gumppes* [LocSg] 'Matthew is afraid of the wolf'); the comitative also expresses the instrument argument. In addition to determinative (e.g., *Máhte* [GenSg] *govva* 'Matthew's picture') and complementing uses (e.g., *seainni* [GenSg] *čađa* 'through the wall'), the genitive expresses the owner argument when the theme is definite, e.g., *beana* [NomSg] *lea áhči* [GenSg] 'the dog is father's'; if the theme is nondefinite, the

locative (< inessive) is the case of the owner argument, e.g., *áhčis* [LocSg] *lea beana* [NomSg] 'father has a dog'; in South Saami, genitive is used in both cases *aehtjien* [GenSg] *bïenje* [NomSg] 'father has a dog,' *bïenje aehtjien* 'the dog is father's.'

Saami phonology is an extreme sport: a bisyllabic stem may have over 20 different phonological forms depending on grade alternation, compensatory lengthening, vowel balance and metaphony, etc., caused by different suffixes. The number of consonant phonemes is 19–40 depending on idiom, and the basic vowel phonemes (5–10 depending on idiom) are combined to form vowel sequences (5–10 geminate vowels and 4–10 diphthongs with the first component higher than the second, e.g., /ie/ and /oa/). Word stress is trochaic, e.g., /kú.laa.hàl.laa.pèeh.teh/ 'you understand each other,' but morphology may cause deviations from the rule, e.g., /múj.j.hta.liš.kòah.tiih/ 'to begin telling' (/-š.kòah.tii-/ is a derivational ending). Ume, Pite, Lule, North, Inari, and Ter Saami have three degrees of quantity in consonants, e.g., North Saami /čáal.l.liih/ 'writers' (with an extra syllabic pulse) vs. /čáal.liih/ 'to write' vs. /čáa.liih/ 'make him/her write!' Also vowels in stressed syllables show three contrasting lengths (roughly [a] – [a·] – [a:]) but these derive from the phonological oppositions (a) single vowel vs. vowel sequence and (b) initial vs. final stress in a vowel sequence, e.g., /sáh.te/ 'haphazard' – /(ij) maáh.te/ 'does (not) know how to' – /máah.te/ 'Matthew's (GenSg)' (phonetically [sahte] – [ma·hte] – [ma:hte]); initial vs. final stress is also found in diphthongs, e.g., /sóa.đan/ 'I fight' vs. /poá.đan/ 'I come.' These contrasts originate in the grammaticalization of allegro forms in which vowel sequences in stressed syllables receive final stress, and vowel sequences in the following syllables are reduced to single vowels (*/póa.đaan/>/poá.đan/ 'I come'). Syllable border placement is distinctive in at least North Saami, e.g., eastern North Saami /pól.htuuh/ 'to rummage' vs. /pólh.tuuh/ 'you rummage.'

Sacks, Harvey (1935–1975)

W Bublitz, Universitaet Augsburg, Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Harvey Sacks graduated from Columbia College, New York in 1955 and earned his Bachelor of Law at Yale Law School in 1959 and his Ph.D. in sociology at the University of California, Berkeley in 1966. Aged 40, he died in an automobile accident in California, where he had taught at the University of California in both Los Angeles and Irvine since 1963. Sacks is best known for his invention of 'conversation analysis.' Even though he published relatively little in his lifetime, his ideas spread continually, chiefly through his numerous university lectures and conference papers; his influence expanded greatly when his lectures were published posthumously in 1992.

Most consequential for the development of his highly original accomplishments in sociology and linguistics was his contact with Harold Garfinkel (and his ideas on ethnomethodology) and Erving Goffman. The influence of Goffman's work in interaction analysis, i.e., the description of how participants behave in normal, everyday interactive encounters, is particularly evident in Sacks's early studies (on suicide help conversations), in which he began to move away from the established quantitative techniques and preanalytic methodology of mainstream American sociology. Instead, he adopted central concepts of ethnomethodology, which is chiefly concerned with the means and methods employed by interactants to create and act within their own social reality. Accordingly, he strongly argued against the widely shared belief that social norms, roles, and rules are statically and objectively given, prior to and independent of the interactants' verbal (and accompanying non-verbal) behavior, in which they are merely reflected. Being convinced that, on the contrary, social order is continuously achieved in social encounters by the participants' skillful use of language, he introduced 'conversation analysis' as an alternative (and by

locative (< inessive) is the case of the owner argument, e.g., *áhčis* [LocSg] *lea beana* [NomSg] 'father has a dog'; in South Saami, genitive is used in both cases *aehtjien* [GenSg] *bïenje* [NomSg] 'father has a dog,' *bïenje aehtjien* 'the dog is father's.'

Sacks, Harvey (1935–1975)

W Bublitz, Universitaet Augsburg, Augsburg, Germany

© 2006 Elsevier Ltd. All rights reserved.

Harvey Sacks graduated from Columbia College, New York in 1955 and earned his Bachelor of Law at Yale Law School in 1959 and his Ph.D. in sociology at the University of California, Berkeley in 1966. Aged 40, he died in an automobile accident in California, where he had taught at the University of California in both Los Angeles and Irvine since 1963. Sacks is best known for his invention of 'conversation analysis.' Even though he published relatively little in his lifetime, his ideas spread continually, chiefly through his numerous university lectures and conference papers; his influence expanded greatly when his lectures were published posthumously in 1992.

Most consequential for the development of his highly original accomplishments in sociology and linguistics was his contact with Harold Garfinkel (and his ideas on ethnomethodology) and Erving Goffman. The influence of Goffman's work in interaction analysis, i.e., the description of how participants behave in normal, everyday interactive encounters, is particularly evident in Sacks's early studies (on suicide help conversations), in which he began to move away from the established quantitative techniques and preanalytic methodology of mainstream American sociology. Instead, he adopted central concepts of ethnomethodology, which is chiefly concerned with the means and methods employed by interactants to create and act within their own social reality. Accordingly, he strongly argued against the widely shared belief that social norms, roles, and rules are statically and objectively given, prior to and independent of the interactants' verbal (and accompanying non-verbal) behavior, in which they are merely reflected. Being convinced that, on the contrary, social order is continuously achieved in social encounters by the participants' skillful use of language, he introduced 'conversation analysis' as an alternative (and by

now major) approach. His aim was to prove that social norms are most adequately described not from a global but from a local point of view. The analyst's task is to meticulously describe the minute details of as many instances of ordinary everyday conversational events (telephone conversations, newspaper stories, jokes) as possible in order to discover systematically recurrent patterns of methods and means that interactants use collaboratively and routinely to negotiate, i.e., establish, maintain, and vary, social order. Conversation analysis is thus an inductive and strictly empirical data- though not theory-driven approach. Preexisting theories with their descriptive categories and rules, which have been independently developed for unspecified sets of data, are rejected as being neither necessary nor applicable to the analysis of naturally occurring (recorded and transcribed) discourse. Instead, analysts develop the necessary descriptive categories while analyzing the data; categories arise in and out of the analytical process and are based on observation, not intuition.

Conceptual landmarks of Sacks's studies of the mechanisms of talk-in-interaction include turn-taking organization (how and where speaking turns occur, how speakers select others or are selected themselves as next speakers, how turns are structured, etc.), topic organization, opening and closing procedures, mechanisms of self-correction and repair, preferred ways of referring to other people and telling stories in conversation, and the sequential organization of conversation with 'adjacency pair' as its key concept. These are pairs of speech acts whose first part sets up a slot with a 'conditional relevance' for an expected, i.e., preferred, second part, thus constraining the interlocutor's choice; examples are question–answer, statement–agreement or – contradiction, invitation–acceptance or – decline, reproach–justification, and also greeting–greeting. It follows that each contribution to an ongoing conversation is both responsive and initiative. By simultaneously taking up the preceding and setting up expectations for the following turn, each interactant reveals his or her understanding of what is going on, what activities are currently performed, and what interactional frames are shared. In this way, participants continually display their awareness of how their use of language contributes to the constitution of the social event they are engaged in. In his later work (from 1968 onward), Sacks broadened his perspective and preferred a more global to the earlier local, occasionally *ad hoc*, and detailed approach to conversational interaction; his work took "a turn toward systematicity and toward the relevance of substantial amounts of data" (Schegloff, 1992b: xi).

Summing up Sacks's legacy, Schegloff lists four aspects: methodology ("of how to study human sociality"), topic (the "recognition . . . that talk can be examined in its own right, and not merely as a screen on which are projected other processes"), discipline, and inspiration (Schegloff,1992a: xii ff.). However, even though the richness, originality, and intellectual vigor of his work together with his "ability to turn the apparently trivial into the gripping and insightful" (Silverman, 1998: x) are apparent from the available oeuvre, the significance of his beliefs is not generally recognized (Silverman, 1998). Not surprisingly, the methods of conversation analysis (being rigorously empirical, inductive, and interactant centered) have also been criticized as being too positivistic, operating in an interest-, ideology-, and culture-free vacuum.

Sacred Texts: Hermeneutics

W W Klein, Denver Seminary, Denver, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The task of hermeneutics involves interpretation, and as a discipline, it concerns the theories and process of understanding. How does anyone come to understand specific human communication, and what is involved when they do? What do readers mean when they say that something has meaning? While such philosophical questions arise with all kinds of inquiries, what is entailed in the understanding of sacred texts, and more specifically, the Bible? In what sense does the Bible have meaning for readers?

On one hand, understanding the Bible is analogous to what occurs in reading any other document – even though this one is ancient. Employing various historical and critical procedures, scholars translate its words into those others can understand. On the other hand, the Bible is a sacred text to Jews (the Hebrew/Aramaic portion) (*see* **Jewish Languages**) and Christians (the Old and New Testaments). For some of these readers, the designation 'sacred text' may indicate simply that the Bible is a foundational document that has priority among all sources of knowledge or inspiration. For others, however, sacred text conveys a more literal belief that the Bible was inspired by God and exists as divine revelation. There are variations of these two positions. Thus the Bible is subject to very different kinds of readings, depending on the readers' views of its nature. How then do readers make sense of the Bible? Since crucial delimitations must restrict the range of this essay, I will focus my attention on Christian readers, and especially Christians in the postreformation period.

Historical Overview

Though the term 'hermeneutics' first appears only in the mid-17th century, the quest to explain how to understand the Bible began with the earliest Christians. Building on their Hebrew heritage, the New Testament (NT) writers themselves started the process of reading and interpreting their sacred text, what Christians came to call the Old Testament (OT), for its significance in light of their experience of Jesus. Luke says of Jesus: "Then beginning with Moses and all the prophets, he **interpreted** to them the things about himself in all the scriptures" (Luke 24:27; NRSV; emphasis added). Jewish rabbinic interpreters employed such tactics as: *midrash* 'interpretation' to find meanings in texts beyond the surface meaning; *pesher*, used at Qumran to unpack the mysteries in the sacred texts that explained their own experiences; allegory, to extract deeper and often multiple senses of the literal sense of texts; and typology, the belief that the Bible reflected patterns of God's working in history. Arguably the authors of the NT employed some or all of these same tactics when they interpreted the OT.

Not surprisingly, then, the next generations of Christians continued these same tactics, especially after they adopted a canon consisting of both the Hebrew Scriptures and what came to be the NT. Though the process was far from tidy, by the council of Carthage (397 A.D.) the fixed collection of 66 books emerged as the Christian Bible (though see below on the extent of the canon). Acknowledged as God's complete revelation, these books continued to be mined for their values for the church. A central concern was to explain and defend orthodoxy as it was developing – especially in opposition to the threats from various sects and heresies, such as Gnosticism.

During the centuries of the early church and into the Middle Ages, scholars interpreted the Bible in a wide variety of ways. Some sought the historical (or literal) sense of a text; Origen detected three senses, and John Cassian found four levels of meaning in a text: the literal, allegorical (doctrinal), moral (tropological), and anagogical (eschatological). The latter two reasoned that the meaning of Spirit-inspired texts could not be limited to what they had meant to the original writers or readers. In addition, for some medieval theologians, when the

Sacred Texts: Hermeneutics

W W Klein, Denver Seminary, Denver, CO, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The task of hermeneutics involves interpretation, and as a discipline, it concerns the theories and process of understanding. How does anyone come to understand specific human communication, and what is involved when they do? What do readers mean when they say that something has meaning? While such philosophical questions arise with all kinds of inquiries, what is entailed in the understanding of sacred texts, and more specifically, the Bible? In what sense does the Bible have meaning for readers?

On one hand, understanding the Bible is analogous to what occurs in reading any other document – even though this one is ancient. Employing various historical and critical procedures, scholars translate its words into those others can understand. On the other hand, the Bible is a sacred text to Jews (the Hebrew/Aramaic portion) (*see* **Jewish Languages**) and Christians (the Old and New Testaments). For some of these readers, the designation 'sacred text' may indicate simply that the Bible is a foundational document that has priority among all sources of knowledge or inspiration. For others, however, sacred text conveys a more literal belief that the Bible was inspired by God and exists as divine revelation. There are variations of these two positions. Thus the Bible is subject to very different kinds of readings, depending on the readers' views of its nature. How then do readers make sense of the Bible? Since crucial delimitations must restrict the range of this essay, I will focus my attention on Christian readers, and especially Christians in the postreformation period.

Historical Overview

Though the term 'hermeneutics' first appears only in the mid-17th century, the quest to explain how to understand the Bible began with the earliest Christians. Building on their Hebrew heritage, the New Testament (NT) writers themselves started the process of reading and interpreting their sacred text, what Christians came to call the Old Testament (OT), for its significance in light of their experience of Jesus. Luke says of Jesus: "Then beginning with Moses and all the prophets, he **interpreted** to them the things about himself in all the scriptures" (Luke 24:27; NRSV; emphasis added). Jewish rabbinic interpreters employed such tactics as: *midrash* 'interpretation' to find meanings in texts beyond the surface meaning; *pesher*, used at Qumran to unpack the mysteries in the sacred texts that explained their own experiences; allegory, to extract deeper and often multiple senses of the literal sense of texts; and typology, the belief that the Bible reflected patterns of God's working in history. Arguably the authors of the NT employed some or all of these same tactics when they interpreted the OT.

Not surprisingly, then, the next generations of Christians continued these same tactics, especially after they adopted a canon consisting of both the Hebrew Scriptures and what came to be the NT. Though the process was far from tidy, by the council of Carthage (397 A.D.) the fixed collection of 66 books emerged as the Christian Bible (though see below on the extent of the canon). Acknowledged as God's complete revelation, these books continued to be mined for their values for the church. A central concern was to explain and defend orthodoxy as it was developing – especially in opposition to the threats from various sects and heresies, such as Gnosticism.

During the centuries of the early church and into the Middle Ages, scholars interpreted the Bible in a wide variety of ways. Some sought the historical (or literal) sense of a text; Origen detected three senses, and John Cassian found four levels of meaning in a text: the literal, allegorical (doctrinal), moral (tropological), and anagogical (eschatological). The latter two reasoned that the meaning of Spirit-inspired texts could not be limited to what they had meant to the original writers or readers. In addition, for some medieval theologians, when the

literal sense of a text did not suffice to defend orthodoxy, they found a level of meaning below the surface. The 'spiritual reading' (*lectio divina*) of texts also developed in this period. Here the goal was not to understand the historical meaning of a text; *lectio* served purposes of devotional edification and meditation.

The Protestant Reformation, coupled with the Renaissance, began the shift toward the 'modern' reading of Scripture. Martin Luther (*see* **Luther, Martin (1483–1546)**) differed from Rome on the fundamental locus of authority. Instead of relying on Scripture plus tradition (often resorting to these arcane methods of interpreting Scripture as the Roman church did), Luther insisted on appealing to Scripture alone (*sola scriptura*) as the channel of God's word and will for the church. He translated the Hebrew and Greek testaments into German – again to liberate God's word from the strictures of the Latin Vulgate. This act energized a renewed emphasis on finding the meaning of the Biblical texts themselves, and not the church's interpretation. On another front, the Renaissance spurred a new interest in classical learning, and called for a return to the original Hebrew and Greek manuscripts of the Bible. The Roman church rejected this challenge to its authority, reaffirming its control over biblical interpretation.

After Luther, William Tyndale (*see* **Tyndale, William (1494–1536)**) and King James of England brought the Bible into English – the Authorized Version appeared in 1611 – and it later was translated into numerous other languages. Many more Christians possessed and read the Bible for themselves – free to do with it whatever they willed. Devotional uses of the Bible paralleled many of earlier pre-Enlightenment uses. Yet the 'rational' reading of the Bible became the central legacy of the postreformation period. In the 19th century and beyond, Rationalism led to the proliferation of critical methods for studying the Bible. Interpretation was freed from all the constraints of dogma and orthodoxy. Studied from a naturalistic worldview that excluded supernatural phenomena by definition, the world of the Bible emerged as a natural one devoid of miracles. The Bible itself was viewed as merely a collection of religious writings on a par with the sacred texts of other religions. Emerging scientific methods gave scholars access to facts and evidence of material culture independent of the statements in the Bible. Some used these methods to call into question the historical reliability of the Bible. For many the Bible became merely a good source for moral or ethical values, not for theological or historical truths. Certainly not all scholars agreed with these dominant trends. In Germany, the British Isles, and North America, prominent scholars resisted some of these trends, insisted on the reliability of the biblical documents, and sought to refute some of the critical conclusions of the strict rationalists.

In the last century, further developments have altered the agendas of Bible interpreters. The focus began to shift from the biblical text as the object of study to the reader as the one who 'produces' meaning. Skeptical about the possibility of objective knowledge, some scholars discounted the ability of readers to find fixed meaning in ancient texts. Because readers are subjective beings, only in their application of texts to concrete situations do they come to understand what those texts mean for them. More recently, embracing postmodernist values (*see* **Postmodernism**), others insisted that readers jettison all attempts to discover objective meanings residing in the texts or the authors of those texts. They championed the meaning produced by the reader – thus the popularity of reader-response criticism. Escaping what they viewed as the restricted and arid confines of historical criticism, many scholars employed other kinds of scrutiny of the biblical texts: literary and rhetorical criticism, psychological exegesis, deconstruction (*see* **Poststructuralism and Deconstruction**), various advocacy criticisms (e.g., feminist, liberationist, Marxist, 'Queer,' or other types of criticism), and social-scientific analyses, among others (*see* **Literary Theory and Stylistics**). At the same time, many conservative readers embraced the new tactics for understanding the ways texts work (such as literary and rhetorical criticism) (*see* **Rhetorical Structure Theory**) without abandoning the essential historicist goal of seeking the text's and author's intentions.

The 'interpretive community' then assumes critical importance for biblical interpretation because each community determines its rules of engagement. One is the community of biblical scholars. Yet each group of scholars within that larger community – whether conservative or liberal – sets its research agenda and governs acceptable findings. A community of believers provides other interpretive constraints – whether the community understands the Bible as a repository of divine revelation (believing the Bible teaches authoritatively) or holds to a more nuanced stance (differing for each community). Finally, to limit the list to three, there is the global or societal community, for the Bible has passed into the larger culture in many parts of the world.

This essay will now outline how a believing community seeks to understand the Bible – those faithful people who read the Bible as a sacred text for them. The 'believing community' occupies the best position to understand the Bible on its own terms – the way, in fact, that most human communication is designed and intended to be understood. I argue that this approach comports most adequately with the putative

purpose of the Bible, the stance of its authors, and the historical view of the church. I reject the epistemological claim that no interpretation can ever be the correct one. Most Christians read the Bible with a view to understanding its meaning for themselves; they come to it positively and openly desire to learn and grow through their engagement with its message. Usually Christians who expend the energy to read and understand the Bible do so because they possess a cluster of qualifications for this enterprise: a reasoned faith that believes the Bible contains value for them; a stance of obedience or a willingness to learn from the Bible; a belief in the illumination of the Holy Spirit – that the Spirit will enable them to embrace or implement the Bible's wisdom; participation in a believing community in some meaningful way; and the willingness to employ appropriate methods for understanding. Stating this list is not to deny, however, that many read and understand the Bible who do not possess some, or perhaps any, of these qualifications. Using appropriate methods, others may understand what the Bible's authors sought to communicate. I simply argue here that believers are in the best position to understand its message from the inside.

The Extent of the Canon

What is the Bible, or in other terms, what constitutes the Christians' sacred text to be interpreted? In simplest terms, Protestant Christians have never agreed with Roman Catholics and Orthodox Christians on the extent of the canon of the OT. On the other hand, all wings of Christendom since the 4th century agree on the contents of the NT. Taking the position of the Jews of the 1st century A.D., Protestants limit the OT to 39 books and exclude the apocryphal or deutero-canonical books that the Catholics and Eastern Orthodox churches embrace. Though these secondary books contain valuable historical information about the Jews in the intertestamental period and though they were influential in the first 1500 years of the church's existence, their influence has waned. For more on the issues of the canon, see the article on the Bible (*see* **Bible**).

Definition of Hermeneutics

In the Gospel of Luke, the author notes that Jesus explained to the two disciples on the road to Emmaus what the Scripture said about him (Luke 24:27). Based on this explanatory function, and transliterating this Greek word *hermeneuō*, hermeneutics as a discipline concerns the principles and theory behind the process of understanding or interpreting human communication, and the cluster of tactics employed to implement that theory. Because the biblical documents derive from worlds very different from that of modern readers – spanning great distances of time, culture, and language – we require an appropriate and defensible procedure to help us understand them.

What should be the agenda for those who wish to interpret the Bible? What ought they seek? Some may despair of any valid interpretation, be content merely to read in their own meanings, be willing to allow all readings to be valid understandings of a text (see our discussion above), or seek the intended meaning of the author and the resulting written text. And there are other options. Three questions immediately surface before interpreters can settle on an agenda. First, since all interpreters bring their presuppositions and preunderstandings to a text, what role do these have in the interpretive process? Second, who gets to decide upon the goal? Third, is the historical meaning of the text the only meaning contained within it? I must develop each of these points briefly.

First, all readers bring who they are to the task of interpretation; indeed without some prior understanding, new understanding is all but impossible. So readers bring their presuppositions about the nature of the Bible and what their study of the Bible entails. They possess varied kinds of information, attitudes, ideologies, and competence in using the methods for explaining texts. But these neither guarantee nor preclude an accurate understanding of a biblical text. In principle at least, readers can overcome all deficiencies in knowledge, ideology, and methodology if they are willing and able to learn and employ what is required to understand an ancient text. The process of understanding allows growth and progress; interpreters do not merely enter a vicious hermeneutical circle in which they come out where they began. Instead, at least in principle, they can enter a hermeneutical spiral that allows them to grow and learn in understanding. Even unlettered Christians can comprehend much of the basic message of the Bible, though their deficiencies may prevent full understanding of many things. Yet those deficiencies, in principle again, can be addressed.

Second, the decision about the goal comes down to how communication functions. While different answers are possible, I contend that the goal of interpretation is to discern what the biblical authors or editors intended to convey in their messages – at least to the extent that such intentions can be recovered in their texts. As noted above, most readers adopt this stance when they seek to understand the Bible – or any communication. While many theorists speak of readers creating or inventing meaning in their

encounter with a text, I believe the most adequate way to understand what a text means is to seek to discover what the author intended to say. That is, I assert we readers ought to treat the biblical text with dignity and respect, as we treat people and their words when we engage in the communication process: we seek to understand what people mean when they speak. Biblical interpretation then succeeds when readers come as close as possible to deciphering the historical meaning of a text (what the author or editor and recipients of the original text would have understood it to mean) and then apply in a valid way the significance of that meaning to Christians today.

For example, consider words attributed to Jesus: "They do all their deeds to be seen by others; for they make their phylacteries broad and their fringes long" (Matt. 23:5; NRSV). Neither the most pious and prayerful meditation nor the most intuitive reader-response reading will achieve an understanding of the meaning and potential significance of Jesus' reference here. Seeking its meaning for Jesus, Matthew, and the original readers must be the goal for those who wish to understand the meaning of the text. This aim also reflects biblical interpretation at its best throughout the history of the church. Most Christians believe this kind of interpretation is what they are doing, even when, wittingly or unwittingly, they are doing some version of reader-response reading – whether from the deconstructionist left or the fundamentalist right.

The third issue on the agenda for determining the goal of biblical interpretation is the question of whether there is only a single meaning resident in a biblical text. It is crucial to distinguish between meaning and significance. By meaning I refer to what the author intended to convey in the words employed in a text. Significance refers to the variety of ways that meaning finds relevance at the time of the writing, in different contexts, and over subsequent centuries. Christians have often used the term 'application' to refer to this second category. So, in insisting that a text has but one meaning, I do not deny that it may have many applications through history. Another way to ask this question is whether, when authors write, they intend their words to communicate a single sense or multiple senses. But perhaps I must extend the question: when the biblical authors wrote, did they write texts capable of a single or multiple meanings? As to the first point, though readers can construe meaning differently – after all, words once written are out there for any to do as they wish – normal communication assumes that authors intend a single sense. That meaning may be intentionally (or unintentionally) ambiguous or may be conveyed through an intentionally nonliteral device or genre (e.g., metaphor or parable), but that ambiguity or figure of speech still describes what the author set out to accomplish.

Any communicative act has content (the message), energy (illocutionary force), and purpose (perlocutionary effect) (*See* **Mood, Clause Types, and Illocutionary Force**). The author selects the best genre to encode the message it order to accomplish these purposes. To understand the meaning in a text, therefore, requires that interpreters give full attention to these dimensions. They are not free to exclude the author when they seek the text's meaning – that is, if they conceive the biblical text as intended by its author to communicate some deliberate message. This inclusion is all the more crucial for those who believe the Bible to be inspired Scripture – in which case God also speaks through it. How can they listen to God speaking through the Bible if they exclude the author's intention as the goal?

Some argue that in biblical texts, the Holy Spirit encoded meanings apart from the human author's intention – a meaning called the *Sensus Plenior*, a fuller sense. As mentioned above, in the past, interpreters sometimes found three or even four levels of meaning in texts. But was that valid? There is no rational or nonrational way to test such a presumption. How would any reader of the Bible discern meanings beyond what normal means of analysis can uncover? The magisterium of the church may well endorse certain interpretations even though they depart from the normal sense of texts. Or an individual faith community could well authorize a meaning that others beyond it would dispute. But apart from such authoritative pronouncements, Christians have no objective way to discover whether any text they read has some deeper meaning(s) below the surface. So while theoretically other levels of meaning may exist (even purportedly put there by the Holy Spirit), readers have no means of detecting it – or, if there come to be rival claims to an alleged deeper meaning – of adjudicating between alternative interpretations.

The task is not always easy, for we are far-removed from the time, culture, and location of the original writers and readers. The distances may be great, but they are not insurmountable. Due to advances in historical, linguistic, archaeological, cultural, and many other kinds of studies, modern readers are now in a position to know much about the ancient world. And with this increasing fund of knowledge and critical expertise, current readers are in a excellent position to understand the world in which the biblical texts emerged. Errors can be committed; presuppositions may derail adequate assessments;

preunderstandings may blind some from seeing clearly what is there – all these and other pitfalls remain as significant challenges to an adequate understanding of the Bible. But in the pursuit of the Bible's meaning, our options are not limited to a free-for-all, anything-goes on one side, or a pessimistic nothing-can-be-known-for-sure on the other. Hard work is involved, but I contend that the essential goal is to understand the meanings of the authors to the extent interpreters can recover them from their texts.

Essential Tasks for Understanding

The pursuit of a text's historical meaning involves five basic steps. The likeliest candidate for the correct meaning of a text is most consistent with these: the literary context in which the text occurs, the features of the culture at the time in which the text emerged, the correct meanings of the words at the time they were used, the proper understanding of how the language was employed grammatically to construct the meaning, and the genre of the text itself. I give attention to each of these points in turn.

Literary Context

Any biblical text – whether a verse, a paragraph, or a larger section – exists within a literary context that flows from one section and into the next. Interpreting a text apart from its context runs the risk of misunderstanding its meaning. One cannot understand the intended meaning of the sentence, "That was the largest trunk I ever saw," apart from the sentences that precede or follow it. The context provides an understanding of the theme or topic of the discussion, gives readers the probable meanings of the words, and enables one to follow the structure or flow of the argument or narrative. Thus, the correct meaning of a passage is the meaning that best fits the literary context in which it occurs.

Literary context also involves moving beyond the immediate context of a text to its place within a larger section of the book, to the context of the entire biblical book in which it occurs, to other books written by the author, if such other books exist in the canon, and to other books written in that same genre, again, if such exist. Canon criticism reminds us that ultimately the canon itself occupies the largest literary context that may shed light on a text. Obviously, the farther out one moves, the less insight one will get into the precise meaning of the text under study.

Historical–Cultural Background

Since the biblical texts were written so long ago, comprehending their historical meanings requires research into their worlds. To put a biblical book into its context, interpreters must try to understand such data as the identity of the author and his or her circumstances, the recipients' situation, the time of the writing, and the circumstances that elicited the writing. Such knowledge is not always available, but can greatly aid interpreters. Beyond the overall context of a book interpreters must investigate the specific details within the book itself and the particular text under scrutiny. In a text under study, we will need to research features as they surface: the worldview, values, and mindset of the participants; societal structures of the time (marriage, family patterns, roles of men and women); physical and geographical features (e.g., climate, means of transportation, elevations); economic structures (wealth, poverty, slavery); political climate (structures, loyalties); behavioral patterns (dress, customs); and religious practices (power centers, rituals, affiliations).

Word Meanings

Words are the basic building blocks of any written communication, and interpreters must ascertain their meanings in a given text (*see* **Lexical Semantics: Overview**). From among the possible meanings of the word at the time, the goal of a word study is to discover the most likely sense in the context in which the author used it. The study of words is fraught with pitfalls, because their meanings change over time, and because most words cover a range of meaning – that is, have multiple senses. Earlier or later meanings of words may be anachronistic or impossible. In the sentence above regarding a large trunk, 'trunk' might refer to a part of a tree or an elephant, a compartment in an automobile (in American English!), a large version of a suitcase, or a transportation system. Here, the literary or historical context in which the sentence occurred will help settle the issue. For texts in the ancient worlds – whether in the OT Hebrew and Aramaic, or the NT Greek – we must access the best lexicons and other historical research to enable us to settle on the most likely sense for the biblical words in the specific contexts under study.

Grammatical-Structural Relationships

Since written languages communicate by combining words into larger units – sentences, paragraphs, sections, discourses, books – a correct understanding of the meaning of a text will fully account for these grammatical and structural features of a language (*see* **Narrative: Linguistic and Structural Theories**). The interpreters in the best position to recognize these features have learned the biblical languages. They seek to explain how things work from within the requirements

of that language – whether Hebrew, Aramaic, or Greek. Many critical commentaries make available the best insights of grammatical analysis to readers. The comparison of several translations also helps readers grasp the essential structures of a passage. Readers should identify the natural divisions in a section, grasp the organization of the argument, the impact of the key verbs, and any other features of the grammar and structure that shed light on the meaning of a passage.

Genre

Though encountered as one book, the Bible includes many books of distinct literary genres written over a period of more than a thousand years. Competent readers of the Bible will seek to become attentive to the ways its messages are conveyed through these various genres. Readers of the OT find narratives of various kinds, legal materials, poetry, prophecy, apocalyptic, and wisdom literature – along with various subcategories such as proverbs, riddles, parables, songs, and lists. In the NT, readers encounter gospels (theological biographies of Jesus), epistles (letters), narrative (Acts, sometimes termed 'theological history'), and apocalyptic (Revelations). Of course, within some of these categories are parables, miracle stories, hymns, vice and virtue lists, and household codes. Each genre or subtype has its own rules of interpretation, and readers must treat each with the integrity and methodology that its form requires. For example, "The mountains and the hills before you shall burst into song, and all the trees of the field shall clap their hands" (Isa. 55:12; NRSV) makes great sense in a poetic utterance, but is unintelligible in a historical narrative. Readers must interpret each genre according to the norms for understanding that kind of writing.

Reading literature responsibly assumes that interpreters understand figures of speech or other literary devices for what they are, and not in some unnatural or literal sense. Again, the intention of the author and the text reigns supreme. Readers should not subvert the meanings of texts or read into them meanings inconsistent with the genre in which they occur.

From Interpretation to Application

Most Bible readers are not content merely to understand what an ancient text means. What a text meant is one thing; its significance in the life of an individual or the church is another. While the meaning of a text is constant and constrained by its sense and the intention of its author (we have argued), it may have further significance (or implications) as Christians apply that meaning to their circumstances. This principle is demonstrated in many biblical texts. For example, Moses assured Israel of God's blessing if the people obeyed God's laws (Deut. 30:11–20). Jesus urged his listeners not merely to hear his words, but to put them into practice (Matt. 7:13–27). Paul goes so far as to say, "For whatever was written in former days was written for our instruction, so that by steadfastness and by the encouragement of the scriptures we might have hope" (Rom. 15:4). Again, "These things happened to them to serve as an example, and they were written down to instruct us, on whom the ends of the ages have come" (1 Cor. 10:11). Many other texts affirm this same dynamic: readers discover the point of Scripture in its application to their lives (*see* **Preaching**).

Application is not so straightforward a task, however. How might a Christian apply the OT injunction not to boil a baby goat in its mother's milk (Exod. 23:19)? Or respond to the prohibition against tattoos (Leviticus 19:28)? Or to the claim that long hair on a man is degrading (1 Cor. 11:14)? Chaos often reigns when individuals or preachers draw out implications of texts. Some rightly ask, why argue for some fixed (original) meaning of texts, when in actual practice Christians apply them in a dizzying variety of ways or no way at all. Further, even if Paul argued against homosexual practice (Rom. 1:24–28), are Christians bound to apply his rule in the same explicit way he did?

As not all interpretations of the meaning of a text are accurate, so not all applications (of even the correct interpretation) are legitimate. But four steps put a modern reader in an excellent position to draw out a legitimate application of a biblical text. Though these scarcely scratch the surface, they are essential: (1) Discover if in its original context the author makes a specific application of the text under study. (2) After assessing the specificity of the original application, determine whether adopting the same application today would convey the same meaning to modern Christians as did the original meaning to the first hearers. If so, then seek the culturally relevant way of implementing that application. (3) If the specific original application cannot be transferred to a modern context and still bear the original significance it had for the original readers, then seek to extract any broader principles that the text conveyed. (4) If possible, apply these principles in a manner that would embody or convey the broader principle.

Uses of the Bible

People interpret, implement, and employ the Bible in a wide variety of ways. If interpreters do not confine hermeneutics to the epistemological realm – how one comes to understand or know – but extend it, as

I have, to the process of explaining the biblical texts, then the result is a wide variety of uses. Though the list of uses could grow quite large, I will limit this discussion to the most obvious and widely practiced. Some people are interested in learning more about the worlds and thoughts of the peoples in Bible times. Their objectives may be informational. Some read and study the Bible as literature, whether for personal enjoyment or with some intellectual objectives. For believers in faith communities, the Bible informs their worship – whether personal or corporate – and the church's liturgy since the church's inception. Interpretations of the Bible have served the church in formulating its theology – growing out of the conviction that the Bible constitutes God's revelation to his people. Since Matthew records Jesus' words that his followers are to send disciples to all the nations and teach all Jesus commanded (Matt. 28:19–20), Christians have claimed to based their teaching and preaching on the content of the Bible. Its teachings underlie Christian faith and practice. In the hands of God's people the Bible serves as a resource for counsel and encouragement as well as correction and reproof. It has a truly formative and foundational role for Christians.

Said Ali, Manuel Ida (1861–1953)

E Guimarães, Institute of Language Studies, Unicamp, Sao Paulo Campinas, Brazil

© 2006 Elsevier Ltd. All rights reserved.

Manuel Ida Said Ali is one of the Brazilian linguists whose work marked the first half of the 20th century in Brazil (Bechara, 1954, 1970; Silva Neto, 1955). The descriptive rigor of his work made him an obligatory reference for all linguists in the country. He had originally begun working in the Laemmert & Co. bookstore in Rio de Janeiro, where he came into contact with the Brazilian historian Capistrano de Abreu, who would greatly influence his intellectual life. He was a professor of German (German, Standard) at the *Colégio Pedro II*, the first public institution of basic and intermediary learning in Brazil. This school, founded in 1837, had a pivotal role in the

I have, to the process of explaining the biblical texts, then the result is a wide variety of uses. Though the list of uses could grow quite large, I will limit this discussion to the most obvious and widely practiced. Some people are interested in learning more about the worlds and thoughts of the peoples in Bible times. Their objectives may be informational. Some read and study the Bible as literature, whether for personal enjoyment or with some intellectual objectives. For believers in faith communities, the Bible informs their worship – whether personal or corporate – and the church's liturgy since the church's inception. Interpretations of the Bible have served the church in formulating its theology – growing out of the conviction that the Bible constitutes God's revelation to his people. Since Matthew records Jesus' words that his followers are to send disciples to all the nations and teach all Jesus commanded (Matt. 28:19–20), Christians have claimed to based their teaching and preaching on the content of the Bible. Its teachings underlie Christian faith and practice. In the hands of God's people the Bible serves as a resource for counsel and encouragement as well as correction and reproof. It has a truly formative and foundational role for Christians.

Manuel Ida Said Ali is one of the Brazilian linguists whose work marked the first half of the 20th century in Brazil (Bechara, 1954, 1970; Silva Neto, 1955). The descriptive rigor of his work made him an obligatory reference for all linguists in the country. He had originally begun working in the Laemmert & Co. bookstore in Rio de Janeiro, where he came into contact with the Brazilian historian Capistrano de Abreu, who would greatly influence his intellectual life. He was a professor of German (German, Standard) at the *Colégio Pedro II*, the first public institution of basic and intermediary learning in Brazil. This school, founded in 1837, had a pivotal role in the

studies of the Portuguese language in Brazil during the entire 19th century and a good part of the next. Ali's work, from the beginning, would show an important difference in relation to his contemporaries, due to its descriptive rigor (Câmara, 1961).

It is along this line that he is remembered in Brazilian linguistic history as one who, at the end of the 19th century and beginning of the 20th century, was making detailed descriptions that became classics, regarding the placing of atonic pronouns (a question that motivated many discussions of normative character in Brazil); the use of the personal infinitive (a characteristic particular to the Portuguese language); intonation in Portuguese in Brazil; and the study of what is in general considered the conditional mode and what he characterized as a future form of the preterit (Ali, 1908/1966).

There are also stylistic studies of authors in the Portuguese language, through which he introduces into Brazilian linguistic thought the question of the subject of the language who marks his expressiveness in that which he says (Ali, 1930). This work, *Meios de expressão e Alterações semânticas* ('Means of expression and semantic alterations'), was one of the few specific works on semantics produced in Brazil during the first half of the 20th century.

In Portuguese language studies, he was the author of two other works of great descriptive importance, still relevant today: *Gramática Secundária da Língua Portuguesa* ('Secondary grammar of the Portuguese language,' 1924), intended for teaching the language, and *Gramática Histórica da Língua Portuguesa* ('Historical grammar of the Portuguese language,' 1931), an indispensable work on the history of the Portuguese language (joining two previous works: *Lexiologia do Português Histórico* ('Lexicology of historic Portuguese,' 1921), and *Formação de Palavras e Sintaxe do Português Histórico* ('Formation of words and syntax of historic Portuguese,' 1923). All of his work was clearly marked by a psychological position, including his *Gramática Histórica*. He himself said that the first part of this book wound up being a semantic lexicology, exactly in virtue of this position. In Brazil at that time, where language studies were predominantly grammatical and normative, Ali recognized the need for a practical ('normative') grammar for pedagogical use. For the first time in Brazil, he expressly formulated the distinction between normative and descriptive, scientific grammar.

Claude de Sainliens was the most popular and most prolific of the French instructors in England in the second half of the 16th century, writing a number of instructional texts for French and Italian, along with at least two major French–English dictionaries.

A native of Moulins, France, de Sainliens fled the Wars of Religion early in the 1560s. He may be the M. Claudius who helped John Baret prepare the French part of his trilingual dictionary (*Alvearie*, 1573/74), and some attribute to him the *Dictionarie French and English* (1570).

His general French textbooks were the *French Schoolemaister* (1573) and the *Frenche Littelton* (1576). They represent slightly different philosophies of language instruction, the former presenting grammar and pronunciation rules first, the latter

relegating those to reference status at the end. In 1580 de Sainliens published three texts meant to supplement the *Littelton: De pronuntiatione linguae gallicae* (in which he attacked efforts for orthographic reform), *A Treatise for the declining of verbs*, and a bilingual dictionary, *A Treasurie of the French tong*. In 1593 he considerably expanded the dictionary, retitling it *A Dictionarie French and English*. This dictionary was an important source for Cotgrave's dictionary of 1611. Both schoolbooks remained popular well into the 17th century, with many posthumous editions.

Sajnovics, astronomer and linguist, was born on May 12, 1735, in Tordas, Hungary, the younger son of a well-to-do noble family. He entered the Jesuit Order in 1748, studied philosophy and mathematics at the Universities of Nagyszombat (Czech: Trnava; German: Tyrnau) and Vienna, and astronomy at the Vienna Imperial Observatory (1766). As a member of a team of Austro–Hungarian astronomers, he traveled, in 1769, to the Arctic island of Vardø, there to record the passage of Venus and to measure the earth–sun distance. Sajnovics, having observed a number of similarities between the words used by the indigenous Lapps and Hungarian words, went to study written sources in Copenhagen, which confirmed his theory that the two languages are related. He reported this to the Danish Royal Society, which published his account (Sajnovics, 1770). Unfavorable reaction to his theory in his native country turned Sajnovics away from further language studies, but he continued distinguished research and teaching in astronomy until his death in Buda (now Budapest) on May 4, 1785. He was a member of the Royal Societies of Denmark and Norway.

His model was fully developed and extended to the entire Finno–Ugric family by Sámuel Gyarmathi (*see* **Gyarmathi, Samuel (1751–1830)**).

Salishan Languages

S Thomason, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

The 23 languages of the Salishan family are spoken in the U.S. Northwest and neighboring British Columbia, along the Pacific coast in Washington, Oregon, and British Columbia, and inland to interior British Columbia, the Idaho panhandle, and northwestern Montana. The languages fall into five distinct branches, according to the most commonly accepted subgrouping schema (Czaykowska-Higgins and Kinkade, 1998a; 3): **Bella Coola,** the northernmost language and a one-language branch; **Central** (or **Coast**) **Salish,** comprising Comox–Sliammon (Comox), Pentlatch, Sechelt, Squamish, Halkomelem, Northern Straits, Klallam (Clallam), Nooksack, Lushootseed, and Twana; the **Tsamosan** languages, Quinault, Lower Chehalis, Upper Chehalis, and Cowlitz, located primarily south of the Central Salish languages; **Tillamook,** a one-language branch, spoken in Oregon; and **Interior Salish,** which is divided into two branches: the three Northern Interior languages – Shuswap, Lillooet, and Thompson River Salish – are spoken in interior British Columbia, and the four Southern Interior languages, Colville–Okanagan, Columbian, Coeur d'Alene, and Montana Salish-(a.k.a. Flathead-) Kalispel–Spokane (Kalispel = Pend d'Oreille), are spoken primarily in the interior U.S. Northwest (although Colville–Okanagan is also spoken across the border in Canada). In several instances, as with Montana Salish-Kalispel–Spokane, different tribes speak closely related dialects of a single (nameless) language.

Various proposals have linked the Salishan family genetically to other Northwest languages, but none of these is widely accepted. The isolate Kutenai, which has long been in close contact with some of the Southern Interior languages, is one candidate for a distant relative. Other proposed congeners are the Wakashan and Chemakuan families, also located in the Pacific Northwest; together, Salishan, Wakashan, and Chemakuan comprise the core of the famous Pacific Northwest linguistic area. A number of striking typological features are found in all three of these families (and some of them also in Kutenai); most of the features mentioned below for Salishan also occur in the other two core Pacific Northwest families.

All Salishan languages have rich consonantal inventories that include ejectives, lateral obstruents, velar vs. uvular obstruents, labialized dorsal consonants, and (in some of the languages) glottalized resonants and pharyngeal consonants. Table 1 shows a widely (though not universally) accepted set of Proto–Salishan consonant phonemes (modified from Kroeber, 1999: 7, partly on the basis of comments in Czaykowska-Higgins and Kinkade, 1998a: 51–52). Vowel inventories, in sharp contrast, are relatively simple: Proto–Salishan is generally believed to have had just four vowel phonemes, /i ə a u/.

Table 1 Proto-Salishan Consonant Phonemes

p	t		c	k	k^w	q	q^w			ʔ
p'	t'	ƛ'	c'	k'	$k^{w\prime}$	q'	$q^{w\prime}$			
		ɬ	s	x	x^w	χ	$χ^w$			(h)
m	n									
	(r)	l	y	(ɣ)	w			ʕ	$ʕ^w$	
	(r')	l'	y'	(ɣ')	w'			ʕ'	$ʕ^{w\prime}$	

Salishan phonology displays other striking features as well, notably the presence (in almost all the languages) of very elaborate consonant clusters, as in Montana Salish *Ta qesm'l'm'él'čstmstx^w!* 'Don't play with that!' Another widely shared phonological phenomenon is a sound change, in most of the languages and apparently independently in at least two subgroups, from the velar consonants *k k' x* to alveopalatals *č č' š* (and then sometimes to other consonants later).

Morphologically, Salishan is heavily agglutinative, or polysynthetic. All the languages have many suffixes, including both grammatical suffixes – for example, transitivizers, subject markers, and object makers – and lexical suffixes by the dozens, primarily indicating concrete objects (e.g., 'hand,' 'face/fire,' 'nose/road/cost,' 'round object,' 'root/berry'). Prefixes are not so numerous, though most of the languages have locative prefixes and several others as well. An affix-loaded Montana Salish word, for instance, is *q^{w}o č-taχ^{w}l-m-nt-cút-m-nt-m* 'they came up to me' (lit. 'me to-START-derived.transitive-transitive-reflexive-derived.transitive-transitive-indefinite.agent'). This word contains one locative prefix and six suffixes, with one suffix set, *-m* 'derived transitive' plus *-nt* 'transitive,' repeated after the reflexive suffix etransitivizes the stem.

Reduplication is a prominent morphological process in Salishan, used for such purposes as distributive plural (e.g., Montana Salish *qe č'uč'úw* 'all of us are gone, we left one at a time' vs. *qe č'úw* 'all of us are gone, we left in a group') and diminutive. Salishan languages have pronominal clitics that mark certain subjects (e.g., in intransitive predicates), suffixes that mark other subjects (e.g., in transitive predicates), suffixes that mark patients, and pronominal possessive affixes (see Czaykowska-Higgins and Kinkade, 1998a: 31).

Word classes include at least full words and particles. Because every full word can serve as the predicate of a sentence, some scholars have argued for the absence of a lexical distinction between verbs and nouns (see Kuipers, 1968; Kinkade, 1983; Jelinek, 1998; for the other side of this controversy, see Van Eijk and Hess, 1986; Kroeber, 1999: 33–36). There is general agreement that, if the distinction exists, its morphological and syntactic ramifications are weaker than in most or possibly all language families outside the Pacific Northwest. Salishan languages have suppletive lexical pairs of roots with singular and plural reference, e.g., Montana Salish *čn ʔúłx*^{w} 'I went in' vs. *qeʔ npílš* 'we went in.'

Nearly all Salishan languages are predominantly predicate-initial, mostly VSO but in some languages VOS; word order is rather free. In all the languages transitivity is a major morphosyntactic category, with transitivizing and detransitivizing suffixes, applicatives, causatives, and other complexities; they are head-marking. Jelinek (e.g., 1984) and Jelinek and Demers (e.g., 1994) have proposed that these are pronominal argument languages, with full noun phrases having the status of adjuncts rather than arguments. This claim has been debated vigorously, on both sides of the issue, by Salishanists and other theoreticians.

Research on Salishan languages began early, with wordlists collected by travelers as early as 1810 and the first grammar and dictionary published later in the 19th century – a grammar and a thousand-page two-volume dictionary of Montana Salish (Mengarini, 1961; Mengarini *et al.*, 1877–1879). Modern Salishan linguistics has been flourishing for over half a century, and three especially important surveys have appeared: Thompson, 1979; Czaykowska-Higgins and Kinkade, 1998a and Kroeber, 1999 (in particular Chap. 1). An annual conference, Salish and Neighboring Languages, is held each August, and the conference preprints are a major source for information on the languages. A sizable number of descriptive grammars and dictionaries of various Salishan languages are now available, together with a great many more articles on specific theoretical and descriptive issues, a large monograph on comparative syntax (Kroeber, 1999), and an etymological dictionary (Kuipers, 2002).

All the Salishan languages are gravely endangered. Czaykowska-Higgins and Kinkade (1998a: 64–67) report speaker figures that range from about 500 (for 4 languages) to fewer than 10 (for 9 languages) and 0 (for several now-vanished languages). Language-revitalization efforts are under way, however, for many of the Salishan languages.

Samar-Leyte

J W Lobel, University of Hawai'i, Mānoa, Honolulu, Hawai'i

© 2006 Elsevier Ltd. All rights reserved.

Waray-Waray (Samar-Leyte) is an Austronesian language of the Central Bisayan subgroup of Central Philippine languages. With approximately 3 million speakers, Waray-Waray ranks sixth in terms of number of speakers in the Philippines, fifth in the Central Philippine subgroup, and third in the Visayan Islands. Waray-Waray is spoken in an area that roughly corresponds to the borders of the Eastern Visayas (Region VIII), except for the western coast of Leyte and Biliran and a number of small islands off the northwestern coast of Samar, most of which are Cebuano-speaking, except for Capul Island, which is home to Sama Abaknon, a language of the Sama-Abaknon subgroup.

As a Central Bisayan language, Waray-Waray is most closely related to Ilonggo (Hiligaynon), Capiznon, Masbatenyo, Romblomanon, Central and Southern Sorsoganon, Porohanon, and Bantayanon. Outside of the Central Bisayan subgroup, these languages are related to Cebuano, Asi (Bantoanon), the Western Bisayan languages (including Aklanon, Kinaray-a, and Unhan [Inonhan]), and the Southern Bisayan languages (including Tausug, Surigaonon, and Butuanon). Within the Central Philippine subgroup, the Bisayan languages are coordinate with Tagalog and the Bikol (Bicolano, Central) languages.

The 'standard' dialect of Waray-Waray is that of Tacloban City. The Waray-Waray-speaking areas exhibit substantial dialect variation, and in many places no two towns speak the same dialect. Approximately two dozen dialects and subdialects are found in the region. The greatest major dividing line is between Northern Samarenyo and the rest of the Waray-Waray area. The dialect of Allen, Samar, is predominantly Southern Sorsoganon mixed with Northern Samarenyo, and neighboring towns also have a considerable amount of borrowing from Southern Sorsoganon. There is also a modest amount of evidence for a split between Samar Waray-Waray and Leyte Waray-Waray, although much of this split consists of borrowings from Cebuano into Leyte Waray. The dialect of Abuyog, Leyte, is particularly heavily influenced by Cebuano, as is the dialect of Culaba, Biliran. It is also interesting that the dialects of the oldest settlements in Baybay, Leyte, (C. Rubino, personal communication), and the Camotes Islands (Wolff, 1967) show a Warayan substratum, indicating that Waray-Waray was much more widespread in previous centuries before the expansion of the Cebuanos in the mid-1800s (Larkin, 1982). In total, there are approximately 25 dialects and subdialects of Waray-Waray, defined mostly by lexical and morphological variation, as very little phonological and grammatical differences exist.

The earliest written works on the Waray-Waray language are Domingo Ezguerra's 1663 grammar *Arte de la Lengua Bisaya de la Provincia de Leite* and a dictionary by Mateo Sanchez (1562–1618) published a century after his death as the *Vocabulario de la Lengua Bisaya* (1711).

Recent works include two dictionaries (Abuyen, 1994; Tramp, 1995), a series of pedagogical texts (Wolff and Wolff, 1967), and two compilations of literature (Luangco, 1982b; Sugbo, 1995). Zorc (1977) contains data from three Waray-Waray dialects in comparison to other Bisayan languages. Waray-Waray is the language of the church throughout the Eastern Visayas region, and by far the most readily available literature in Waray-Waray is religious in nature, including two modern Bible translations and numerous prayer pamphlets.

Waray-Waray has the basic Central Philippine-type phonology, with 16 consonants / p b m w t d n s l r y k g sng_2 $uʔ_S$ h / and three vowels / a i u /, and both stress and length are contrastive. Most of the dialects of northeastern and eastern Samar have a fourth vowel as a reflex of PAn *e, a high, central, tense unrounded vowel ɨ. The Waray-Waray orthography is mostly regular except that it does not represent stress, length, or the glottal stop.

Waray-Waray is most readily distinguishable from other Central Philippine languages by the *s > /h/ sound change that has affected a small number of common grammatical morphemes in all areas of Samar south of the Sta. Margarita-Matuginao-Las Navas-Gamay line and all of Leyte Waray except the towns of Javier and Abuyog. However, the *s > /h/ change and the loss or retention of PAN *e are areal features, and therefore do not define genetic subgroups within Waray-Waray.

Waray-Waray is agglutinative, with a complex system of verbal morphology expressing a wide variety of semantic and syntactic contrasts. Although sometimes analyzed as ergative, these languages are probably of a separate type called Symmetrical Voice Languages, in which multiple voice distinctions exist, yet none can be considered more 'basic' than the other (Himmelmann, to appear). Like most other Philippine languages, there are four main verbal 'focuses' (actor, object, location, and beneficiary; see Table 1) and three 'case' distinctions (nominative,

Table 1 Waray-Waray focus-mood-aspect morphology

		Actor focus	*Object focus (1)*	*Object focus (2)/beneficiary focus*	*Location focus*
-um-verbs	**Infinitive**	-um-	-on	i-	-an
	Past/perfective	-inm- -īn-	-in-	i-. . .-in-	-in-. . .-an
	Present/progressive	nā-	-in-R-	i. . .-in-R-. . .	-in-R-. . .-an
	Future	mā-	R-. . .-on	i-R-	R-. . .-an
	Imperative/subjunctive	ø-	-a	-an	-i
	Future subjunctive	R-	R-. . .-a	R-. . .-an	R-. . .-i
mag-verbs	**Infinitive**	mag-	pag-..-on	ig-	pag-. . .-an
	Past/perfective	nag-	gin-	igin-	gin-. . .-an
	Present/progressive	nag-R-	gin-R-	igin-R–	gin-R-. . .-an
	Future	mag-R-	pag-R-. . .-on	ig-R-	pag-R-. . .-an
	Imperative/subjunctive	pag-	pag-. . .-i	pag-. . .-an	pag-. . .-i
	Future subjunctive	pag-R-	pag-R-. . .-i	pag-R-. . .-an	pag-R-. . .-i

Table 2 Waray-Waray pronouns

		Nominative	*Genitive*	*Oblique*
Singular	**1st**	akó, ak	ko	(ha/sa) ákon
	2nd	ikáw, ka	mo, nímo, nim	(ha/sa) ímo/im
	3rd	hiyá/siyá	niyá	(ha/sa) íya
Plural	**1st exclusive**	kamí	námon	(ha/sa) ámon
	1st inclusive	kitá	náton	(ha/sa) áton
	2nd	kamó	níyo	(ha/sa) íyo
	3rd	hirá/sirá	níra	(ha/sa) íra

Table 3 Waray-Waray case markers

		Standard Waray	*Abuyog*	*Calbayog; Northern Samar-A*	*Northern Samar-B*
Nom	-ref	in	in	in	i(n)
	+ref, +past	an	an	an	a(n)
	+ref, -past	it	it		
Gen	-ref	hin	sin	sin	si(n)
	+ref, +past	han	san	san	sa(n)
	+ref, -past	hit	sit		
Obl		sa	sa	sa	sa

genitive, and oblique) in noun phrases, name phrases, and pronouns (marked by an introductory morpheme) (see Table 2). Nouns, adjectives, and verbs distinguish between singular, plural, and in some cases, dual, and verbs may also be marked for reciprocal action. A number of other meanings can be marked by verbal affixes, including accidental, abilitative, distributive, causative, social, and diminutive. Tense-aspect-mood distinctions include infinitive, past/perfective, present/progressive, future, imperative/subjunctive, and future subjunctive. Both reduplication and repetition are productive mechanisms that can denote diminutive, repetitive, and intensive meanings, among others.

Table 4 Waray-Waray demonstratives

	Nominative	*Genitive*	*Oblique*
Near speaker; far from addressee	adí	hadi/sadi	didi, ngadi
Near speaker and addressee	iní	hini/sini	dinhi, nganhi
Far from speaker; near addressee	iton	hiton/siton	dida, ngada
Far from speaker and addressee	adto	hadto/sadto	didto, ngadto

Waray-Waray has much the same grammatical structure as Tagalog, except for (a) the existence of distinct imperative forms, (b) a preference for inflecting verbs for plural actors, (c) a more elaborate system of case markers that distinguish between referential and non-referential and past and non-past in both the nominative and genitive cases (see Table 3), and (d) a four-way distinction in demonstratives, including a contrast between referents that are near only the speaker vs. those that are near both the speaker and the addressee (see Table 4).

A noteworthy feature of the lexicon of dialects of Waray-Waray spoken in parts of eastern and northeastern Samar is the existence of a register of vocabulary reserved for usage by speakers when they are angry.

Samoa, American: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

A group of five volcanic islands and two coral atolls in the South Pacific Ocean, 14 degrees below the equator, about halfway between Hawaii and New Zealand, American Samoa is the southernmost territory of the United States. Linguistic and cultural evidence suggests that the first Samoa inhabitants migrated from the West, possibly by way of Indonesia, Vanuatu, Fiji and Tonga, to the eastern tip of Tutuila near the present village of Tula around 600 B.C. It is believed that there was at least an 800-year history of contact with Fiji and Tonga before the Samoan islands were officially 'discovered' by Dutch explorer Jacob Roggeveen in 1722. International rivalries in the latter half of the 19th century were settled by an 1899 treaty in which Germany and the United States divided the Samoan archipelago. The United States formally occupied its assigned portion – a smaller group of eastern islands with the harbor of Pago Pago – the following year. The western islands are now the independent state of Samoa. Although technically considered unorganized in that the U.S. Congress has not passed an Organic Act for the territory, American Samoa is self-governing under a constitution that became effective in 1967. The official languages are Samoan and English, with the majority of the population bilingual. The Samoan language is closely related to Hawaiian and other Polynesian languages. There are only minor regional dialect differences, but great phonological and lexical differences, between formal and colloquial speech.

The Independent State of Samoa, situated in the South Pacific Ocean, comprises two main islands and a number of smaller islands and uninhabited islets. Settled as early as 1500 B.C., Samoa was reached by European explorers in the 18th century. International rivalries in the latter half of the 19th century were settled by an 1899 treaty in which Germany and the United States divided the Samoan archipelago. Shortly after the outbreak of World War I in August 1914, New Zealand sent an expeditionary force to seize and occupy German Samoa. This was to stop German Samoa from being used as a naval refueling base in the Pacific. The German forces on the islands did not surrender; nor did they put up a fight. German Samoa was renamed Western Samoa and New Zealand continued the occupation of Western Samoa throughout World War I. In 1919, under the Treaty of Versailles, Germany dropped its claims to the islands and they were granted to New Zealand as a League of Nations mandate. New Zealand administered Western Samoa under the auspices of the League of Nations, and then as a United Nations trusteeship, until the country received its independence in 1962 as Western Samoa. The country was a constitutional monarchy under a native chief, making it the first Polynesian nation to reestablish independence in the 20th century. The country officially changed its name to Samoa in 1997. The official languages are English and Samoan. The Samoan language plays a significant part in the islands' culture; elaborate ceremonies and protocols revolve around it. Samoan presents no significant dialect variations but has important register-based distinctions in the phonology. The talking chiefs' dialect is very different and most Samoans have difficulty understanding it. The language used by the chiefs, who are versed in eloquent speech-making that recalls the village history, genealogy, and proverbs, is very poetical and figurative. Symbolic phrases are used lavishly in speeches during ceremonies and political debates. The everyday language is used by all, including the chiefs during personal conversations and at home.

San Marino: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

A small and completely landlocked enclave in central Italy with a total territory of 61.2 km^2, San Marino claims to be the world's oldest republic, founded by a Christian stonemason named Marinus in 301 C.E. The national language of the Most Serene Republic of San Marino is Italian. The schooling is conducted in Italian and the literacy rate is of circa 98% both for men and women. Aside from Italian, 83% of the 28 503-strong population (July 2004) also speak the Sammarinese dialect of Emiliano-Romagnolo, a language structurally separate from Italian that is related to Lombard, traditionally spoken in Northwest Italy. Sammarinese-speaking adults use Italian as a second language, and there is a 100% literacy rate in the latter. San Marino also has a population of 1455 deaf people. San Marino has one television and three radio stations, which broadcast mainly in Italian, and residents regularly receive broadcasts also from Italy.

Sanchis Guarner, Manuel (1911–1981)

J Carrera-Sabaté, Universitat de Barcelona, Barcelona, Spain

© 2006 Elsevier Ltd. All rights reserved.

Manuel Sanchis Guarner was born in Valencia in 1911. At the age of five, following the death of his father, he was placed under the tutelage of his uncle, the Valencian archaeologist, Josep Sanchis Guarner, from whom he inherited his passion for the study of his own country. Manuel Sanchis Guarner obtained his university degree in Arts and Law at the University of Valencia, became one of the directors of Valencianist Cultural Action, and consolidated his life's project: to dedicate his efforts to his own country.

In 1932, he obtained a grant to work in the Centre for Historical Studies (CEH) in Madrid. In the philology section of the CEH, Sanchis Guarner learned phonetic methodology and dialectology from Menéndez Pidal, Américo Castro, Rafael Lapesa, and Tomás Navarro Tomás, and he acquired the necessary background to lay down the foundation for Valencian philology. In 1933, he agreed to write *La llengua dels valencians*, which became a point of reference in Valencian philology and Valencian identity, as can be seen by its many editions. In 1934, Navarro Tomás asked Sanchis Guarner to join a survey group for an ambitious project which he was directing: The *Linguistic Atlas of the Iberian Peninsula* (ALPI). With this project, Sanchis Guarner made several research journeys to Spanish-, Basque-, and Catalan-speaking lands, the latter with Francesc de Borja Moll.

The atlas project has never been finished because it was interrupted by the Spanish Civil War. Sanchis Guarner was incorporated into the Republican army, and during the war he spent most of his time in Extremadura and Madrid. After the defeat of the Republican army, Sanchis Guarner was held in a concentration camp (Salamanca) and later imprisoned in Madrid. After being a prisoner for nearly four years, he was released provisionally, and in 1943 he settled in Majorca, where he became a language teacher in a high school and took up scientific research again with the support of Francesc de Borja Moll.

During this 16-year Majorcan period, he collaborated with Francesc de Borja Moll in the writing of the *Diccionari Català-Valencià-Balear,* initiated by Antoni M. Alcover. Until that moment, Sanchis Guarner had specialized in phonetics and dialectology, but in working on the dictionary, he learned lexicographic techniques, etymology, semantics, language history, popular culture, and the study of proverbs and proper nouns. He produced different studies in Catalan philology, such as *Introducción a la historia lingüística de Valencia* (1949), *Gramàtica valenciana* (1950), *Els parlars romànics de València i Mallorca anteriors a la Reconquista* (1955), and others, centered on the recovery of local linguistic or literary topics: *Els poetes romàntics de Mallorca* (1950), *Calendari de refranys* (1951), and *Els poetes insulars de postguerra* (1951).

In 1947, Sanchis Guarner and Francesc de Borja Moll resumed interviewing for the ALPI. Sanchis, as one of the main transcribers for the project, traveled to New York in 1951 to retrieve the atlas materials that had been safeguarded by Navarro Tomás since the Spanish Civil War. The publications by Sanchis Guarner relating to the atlas were *La cartografía lingüística en la actualidad* (1953) and the *Atlas de la Península Ibérica* (1953). Furthermore, Sanchis Guarner, as the executive director of the ALPI, presented the publication of the first volume of the atlas at the Congress of Romance Philology in Strasbourg in 1962.

In 1954, Sanchis Guarner began teaching different courses in Valencian language and culture twice a year at the College of Arts at the University of Valencia. In 1959 he definitively returned to his native city, where he worked as a French teacher in a school. Later on, he was placed in charge of the Romance Philology and General Linguistics courses at the university. Afterwards, he became head of the Valencian Linguistics Department, in 1979, and he taught at the university until he retired, in 1981, the same year he passed away. From this period, publications he wrote that were significant include: *Els valencians i la llengua autòctona durant els segles XVI, XVII i XVIII* (1963), *Els pobles valencians parlen els uns dels altres*, 4 vols. (1963–1983), and *Aproximació a la història de la llengua catalana* (1980). He also collaborated on the *Història del País Valencià* (1960–1990).

Sanchis Guarner, as author of numerous papers, prologues, and books reviews, contributed to Catalan philology in several subjects, mainly: dialectology, grammar, history of the language, literature, and culture. Furthermore, throughout his academic life, he participated in different Romance philology congresses and joined the Miguel de Cervantes Institute of Spanish Philology of the CSIC – Consejo Superior de Investigaciones Científicas, the Centre de Cultura Valenciana, the Institut Alfons el Magnànim de Valencia, and the Escola Lul·lística de Mallorca. He

was also a member of the Institut d'Estudis Catalans, the Real Academia de la Historia, the Reial Acadèmia de Bones Lletres, The Hispanic Society of America, and Academia de Bellas Artes de San Fernando. In 1974 he was given the Honour Award of Catalan Letters and in 1981 he received the Award of the Unity of the Language for *Aproximació a la història de la llengua catalana*.

Unfortunately, Sanchis Guarner suffered the effects of numerous stratagems against him by several anti-nationalist sectors in Valencian society. He was even the victim of a frustrated bomb attack. Many people did not forgive the fact that his scientific work made the unity of Catalan clearly evident.

Sanctius, Franciscus (1523–1600)

M Piot, University of Grenoble, Grenoble, France

© 2006 Elsevier Ltd. All rights reserved.

Franciscus Sanctius or Francisco Sánchez de las Brozas, known in Spain as 'El Brocense,' was born c. 1522 in Las Brozas in the Spanish province of Cáceres into an aristocratic or 'hijosdalgo' family that had little economic means. At the age of 11, following his uncles on his mother's side named Sánchez (whose name he at that time assumed), he was trained into the Royal Portuguese household in Evora and then in Lisboa, where he began to study Latin and Classics. Coming back to Spain, he studied at the University of Salamanca and received his Bachelor of Arts in 1551. He was a lecturer in Rhetoric there also and later obtained a Cátedra de prima de Gramática (1564), and then a Chair of Rhetoric (1573) and the Chairs of Greek and Latin (1576). Sanctius married twice thereafter and had 12 sons. Bothered at the end of his life (1585–1595) by the Inquisition Court because of his rebellious and critical stance against indoctrination and conformism, he died in Valladolid in 1600.

He wrote treatises on Rhetoric: *De arte dicendi liber unus* (1556) and *Aphthonii Sophistae Progymnasmata Rhetorica* (1556); on Latin: *Grammatices Latinae Institutiones* (1562) and *Arte para en breve saber latin* (1576); and on Greek: *Grammatica Graeca* (1581). He also composed several works on Dialectic: *Organon Dialecticumm et Rhetoricum* (1579) and *De nonnullis Prphyrii aliorumque in Dialectica erroribus Scholae Dialecticae* (1588); and on philosophy, astronomy, literature, and translation. His work also includes philological comments on ancient writers such as Virgil, Ovidius, Pomponius Mela, Perse and Epicteta and moderns such as Politianus, Garcilaso de la Vega, and Juan de Mena.

In his major work, *Minerva: seu de causis linguae Latinae* (1587), a grammar of Latin whose subtitle he took from his predecessor Julius Scaliger, recognizing the same overall purposes and point of view on grammatical studies, he also referred to Nebrija's humanist work. He shared the same methodological concern about linguistic analysis as Petrus Ramus, and he conversely pointed out a lack of rationality and methodology in the Italian philological tradition exemplified by Valla. He also criticized Erasmus for using a nonclassical Latin.

Following his philosophical stands on Plato's and Aristotle's arbitrariness of motivation of the linguistic units, Sanctius explicitly took his place in the grammatical tradition of Quintilian's and Priscian's syntactic approach, attempting to recover the logical structure of sentences.

The purpose of the *Minerva* was to unearth the origins and logical structures (*causae*) as much as the internal rules (*vera principia*) of this language in order to simplify the multiplicity of uses and methods of language acquisition. Constructing this rule-based grammar, Sanctius, both theoretician and great philologist (he mastered the entire classical Latin corpora and leading grammaticians' works in order to exemplify his views and hypotheses), aimed at a theoretical

He was a lecturer in Rhetoric there also and later obtained a Cátedra de prima de Gramática (1564), and then a Chair of Rhetoric (1573) and the Chairs of Greek and Latin (1576). Sanctius married twice thereafter and had 12 sons. Bothered at the end of his life (1585–1595) by the Inquisition Court because of his rebellious and critical stance against indoctrination and conformism, he died in Valladolid in 1600.

He wrote treatises on Rhetoric: *De arte dicendi liber unus* (1556) and *Aphthonii Sophistae Progymnasmata Rhetorica* (1556); on Latin: *Grammatices Latinae Institutiones* (1562) and *Arte para en breve saber latin* (1576); and on Greek: *Grammatica Graeca* (1581). He also composed several works on Dialectic: *Organon Dialecticumm et Rhetoricum* (1579) and *De nonnullis Prphyrii aliorumque in Dialectica erroribus Scholae Dialecticae* (1588); and on philosophy, astronomy, literature, and translation. His work also includes philological comments on ancient writers such as Virgil, Ovidius, Pomponius Mela, Perse and Epicteta and moderns such as Politianus, Garcilaso de la Vega, and Juan de Mena.

In his major work, *Minerva: seu de causis linguae Latinae* (1587), a grammar of Latin whose subtitle he took from his predecessor Julius Scaliger, recognizing the same overall purposes and point of view on grammatical studies, he also referred to Nebrija's humanist work. He shared the same methodological concern about linguistic analysis as Petrus Ramus, and he conversely pointed out a lack of rationality and methodology in the Italian philological tradition exemplified by Valla. He also criticized Erasmus for using a nonclassical Latin.

Following his philosophical stands on Plato's and Aristotle's arbitrariness of motivation of the linguistic units, Sanctius explicitly took his place in the grammatical tradition of Quintilian's and Priscian's syntactic approach, attempting to recover the logical structure of sentences.

The purpose of the *Minerva* was to unearth the origins and logical structures (*causae*) as much as the internal rules (*vera principia*) of this language in order to simplify the multiplicity of uses and methods of language acquisition. Constructing this rule-based grammar, Sanctius, both theoretician and great philologist (he mastered the entire classical Latin corpora and leading grammaticians' works in order to exemplify his views and hypotheses), aimed at a theoretical

and general analysis of language – using ellipsis as its main tool. His grammar implemented the rebuilding of syntactic elementary structures, most of them regular (*ratio*), although with redundancy and subjected in real language (*usus*) to various deletions. He accurately drew up the 'constraints' list on deletion and operations, such as addition, permutation, or substitution that allows passage from the logical level to the level of speech. Every part of speech that is morphologically well-defined has its own syntactic behavior and invariably remains in its primitive class. The keyword is 'unicity,' notwithstanding surface variations. At some level of the analysis (*oratio perfecta*), all the utterances of the clause's basic structure are composed of a subject (*suppositum*) and an object (*appositum*).

In comparison with his predecessors, he reduced the number of parts of speech and the number of verbal voices to active/passive contrast. Instead of expanding it, Sanctius preferred to clear terminology. He made some references to Greek about rhetorico-grammatical terminology, syntactic uses, etymologies, and some short allusions to Arabic.

The *Minerva* has always provided a wealth of problematics on coordination and subordination, case theory, verbal phrase structure, agreement syntax, polysemy, etc.

The works of Gasparus Scioppius and Jacobus Perizionius contributed to the *Minerva*'s popularity in Italy, the Netherlands, Portugal, Germany, and France during the 17th and 18th centuries. Writing his *Nouvelle Méthode Latine*, Claude Lancelot discovered Sanctius' Latin syntax and principles. Thus, Sanctius's ideas came into the *Grammaire Générale et Raisonnée* of Port-Royal through Lancelot. Later, Sanctius had a lot of direct and major influence on the thinking and work of grammarians in the 18th century. Nicolas Beauzée continued the Port-Royal and especially the Sanctius tradition and principles in his *Grammaire Générale* and the *Encyclopédie*'s grammatical entries he wrote. His overall views reflected Sanctius's theoretical framework, with his keyword: the ellipsis method. The simplicity of its rules and the fact that logical structures assisted in the interpretation of difficult uses of languages had the same didactic implications for Sanctius as for Beauzée. Du Marsais and James Harris's *Hermes* also followed, in part, the Sanctius tradition. After a certain lack of interest in general grammar in the 19th and 20th centuries, the advent of Zellig S. Harris's and then Chomskyan transformational models renewed curiosity in Sanctius's work and the subsequent French general grammars. The *Minerva* is today considered by a number of scholars as prefiguring aspects of Transformational Grammar, and Sanctius and his successors are considered as forerunners of that linguistic school.

Sandhi

E M Kaisse, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

Sandhi is the term used by the ancient Indian grammarians, most notably Pāṇini, to refer to phonological processes occasioned by the putting together (Skt. *saṃ +dhi*) of morphemes to form words, and words to form phrases. Because the sacred Vedic texts were to be transmitted orally, it was important that the hymns be pronounced without change through time; considerable effort was therefore spent in describing the influence of adjacent segments on one another. The grammarians spoke of internal sandhi, the phonology that occurs within words, and of external sandhi, the phonology that occurs between words in connected speech.

and general analysis of language – using ellipsis as its main tool. Sandhi

E M Kaisse, University of Washington, Seattle, WA, USA

© 2006 Elsevier Ltd. All rights reserved.

Sandhi is the term used by the ancient Indian grammarians, most notably Pāṇini, to refer to phonological processes occasioned by the putting together (Skt. *saṃ +dhi*) of morphemes to form words, and words to form phrases. Because the sacred Vedic texts were to be transmitted orally, it was important that the hymns be pronounced without change through time; considerable effort was therefore spent in describing the influence of adjacent segments on one another. The grammarians spoke of internal sandhi, the phonology that occurs within words, and of external sandhi, the phonology that occurs between words in connected speech.

The earliest use of the word in English seems to have been in 1806, when the missionary William Carey, in his published work on Indian grammar, referred to "the permutation of letters occasioned by the junction of syllables" in Sanskrit; Joseph Wright's translation of Brugmann (1888) extended the use of the term to Latin. Gabelentz (1891) was perhaps the first in Western Europe to use sandhi as a term in general linguistics. The American structuralists Edward Sapir (1925) and Leonard Bloomfield (1933) began to use the word as a synonym for 'juncture,' and they are most likely responsible for bringing the term into modern usage.

In the mid–20th century, linguists writing in English about Chinese phonology began regularly to use the term *tone sandhi* to refer to the alterations of tones conditioned by other tones (Shen, 1964; Kratochvil, 1968). It was gradually discovered that identical strings of tones might affect one another differently, depending on the rhythmic and grammatical organization of the words on which the tones fell. Determining the domain in which tone sandhi operates has become a major area of research (Chen, 2000). The sandhi domains differ among Chinese languages, some applying within metrical feet, others operating on larger domains of the prosodic hierarchy, such as phonological words, phonological phrases, and intonational phrases. Since these domains are constructed in part on the basis of syntax, it is frequently necessary to know something about the syntactic structure of a sentence in order to know how the tones will emerge.

In the last quarter of the 20th century, sandhi came to refer almost exclusively to external sandhi, and therefore to be more or less synonymous with phonological processes, both segmental and tonal, operating between words. Well-studied examples include *raddoppiamento sintattico* (gemination of a word-initial consonant) in Italian (Napoli and Nespor, 1979), *liaison* in French (syllabification of a word-final consonant as the onset of the next, vowel-initial word (Selkirk, 1972), and tone sandhi processes in many Bantu languages. Selkirk (1980, 1984), Nespor and Vogel (1986), Kiparsky (1982), and Kaisse (1985) were influential in bringing the study of such processes into the mainstream of generative studies. Selkirk and Nespor and Vogel pioneered work on the prosodic hierarchy as the mediating structure between syntax and phonology, whereas Kaisse took the position that rules of external sandhi could refer directly to an impoverished syntactic structure. Kiparsky divided phonological rules into lexical (word-internal) and postlexical (word-external) processes, each type having a defining set of characteristics. Efforts by Andersen (1986) and Inkelas and Zec (1990), for example, have brought together contributions on the external sandhi of particular languages and their theoretical implications.

Sango

W J Samarin, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Sango was declared the 'national language' in the constitution of the Central African Republic (1964), French alone having the status of 'official language.' Sango also was given this status in 1991, allowing it to be used in governmental communications. In practice, however, it is not yet a legal language and is not used in public education, French being the official medium. Missionaries introduced written Sango in the 1920s, Catholics and Protestants using different orthographies; an official one was established by presidential decree in 1984. Literacy in Sango has been used nonreligiously, primarily in personal correspondence and by radio 'journalists' preparing notes in *ad hoc* orthographies based on religious Sango. There were about 46 hours of broadcasts in Sango in 1994, but most of them were broadcasts of dance music in the Kinshasa style, the rest news and practical information.

Sango is a pidgin in origin, emerging very quickly after representatives of King Leopold II in 1887 arrived to claim land and trade for elephant tusks in the Ubangi river basin, followed in 1889 by the French. Unlike other pidgins, Sango appears to have arisen, not from the attempts of whites to communicate in an indigenous language, but from the attempts of the linguistically diverse African soldiers and workers who were brought to the region for its colonization. The Belgians used many men from the east coast, the French from the west coast, and both many more from the Bantu population along the Congo river. Its existence as a *lingua franca* was noted by Belgians in 1895. It is based on the Ngbandi subfamily of languages (not just the variety called Sango) that make up the larger Ubangian family, to which most of the Central African languages belong. Although its phonology is the same as that of the source language and although most of its lexicon is Ngbandi, it is typically a pidgin in having a very limited vocabulary (from 500 to 1000 words in daily use) and virtually no inflection in its grammar; tone plays a very limited grammatical role and only in the speech of those influenced by Ngbandi speakers, such as the Sangos and Yakomas.

Despite Sango's linguistic limitations, it is a symbol of Central African identity and is by far the preferred language of daily discourse in its capital of one-half million persons, Bangui. However, several Central Africans are active in legitimizing Sango with claims about its adequacy for indigenous culture and with efforts to increase its lexicon with Sango-based neologisms and words from regional languages. Nonetheless, French words occur in all varieties of Sango. The influence of French has increased since independence in vocabulary, grammar, and syntax, even among those with little education.

Although Sango was remarkably uniform as a *lingua franca*, it has become extremely variable as the vernacular of Bangui in all of its structures but exceptionally in its phonology. Contraction creates most of the word variants, as *twa* from *tongana* 'when, if,' resulting in many syllable and word forms that are strikingly different from those of indigenous languages: e.g., *tl* from *tî* 'of' with *l* carrying high tone with words beginning with *l*. Central African activists, however, are striving for a 'standard' (that is, normative or prescriptive) form of the language.

Practically all of the estimated 2 500 000 inhabitants of the Central African Republic speak Sango (according to the census of 1988, varying from 10 to 100%), and in 1994, it was the only language known by about 40–50% of Bangui's preschool non-Muslim children.

The Sanskrit language – one of the oldest of the Indo–European group to possess a substantial literature – has particular interest for linguists because of the circumstances of its becoming known to Western scholars and the stimulus thus given to historical linguistics. It has also been of enormous and continuing importance as the classical language of Indian culture and the sacred language of Hinduism.

Origin and History

Sanskrit, in its older form of Vedic Sanskrit (or simply Vedic), was brought into the northwest of India by the Āryans some time in the second half of the second millennium BC and was at that period relatively little differentiated from its nearest relation within the Indo–European group, Avestan in the Iranian family of languages (these two being the oldest recorded within the Indo–Iranian branch of Indo–European). From there, it spread to the rest of North India as the Āryans enlarged the area that they occupied, developing into the classical form of the language, which subsequently became fixed as the learned language of culture and religion throughout the subcontinent, while the spoken language developed into the various

Prākrits. There is ample evidence of rapid evolution during the Vedic period, with the language of the latest phase, attested for example in the Upanisads, showing considerable grammatical simplification from that of the earliest hymns. The later Vedic is, in broad terms, the form of the language that Pāṇini described with such exactness in his grammar around the fourth century BC, thereby creating – no doubt unintentionally – an absolute standard for the language thereafter; his work is clearly the culmination of a long grammatical tradition, based on concern to preserve the Vedas unaltered (hence the stress on phonetics), and is itself intended for memorization and oral transmission, as its brevity indicates.

This standardization was not as universal as has sometimes been represented (nor was the preceding Vedic a unified language, for it exhibits features only explicable as coming from slightly differing dialects, and classical Sanskrit is based on a more eastern dialect than the one attested in the *Ṛgveda*), and it has come to be recognized that, for example, the two Sanskrit epics exhibit systematic divergences from the language described by Pāṇini and represent a distinct epic dialect. However, with the growth of classical Sanskrit literature (mainly within the period from the fourth to the tenth centuries AD, when Sanskrit was clearly no longer a natural language), Pāṇini's description was regarded as prescriptive and followed to the letter, although the spirit was less closely observed (as shown by the tendency to longer and longer compounds and to nominal constructions and the like).

The earliest record of the language is contained in the hymns of the *Ṛgveda*, which belong to around 1200–1000 BC, but they were not committed to writing until a much later period because of their sacred character, for the Indian tradition has always placed greater emphasis on oral tradition than on written texts. In fact, the earliest dated record in Sanskrit is an inscription of 150 AD, significantly later than the use of Prākrit by the Buddhist ruler Aśoka for his inscriptions in the third century BC. Early inscriptions used one of two scripts: the Kharoṣṭhī, deriving from the Aramaic script used in Achaemenid Iran, and the Brāhmī, less certainly deriving from a North Semitic script. The latter evolved into the Nāgarī family of scripts, to which the Devanāgarī script now usually used for Sanskrit belongs, although before the twentieth-century manuscripts were normally written in the local script.

Characteristics

Any analysis of Sanskrit syntax must take account of the shift from the natural language of the Vedic and epic forms of Sanskrit to the learned language of the classical literature, which selectively exploits certain features of Pāṇini's description. Whereas the older forms of the language show frequent use of nominal compounds of two or three members and Pāṇini's grammar describes their formation in great detail (but in terms of their analysis into types: *dvandva*, *bahuvrīhi*, *tatpuruṣa*), classical literature is marked by a predilection for longer compounds, consisting in some styles of writing of 20 or more members. Another common feature, inherited from the Indo–European background but found much more extensively in the classical language, is the use of nominal sentences involving the juxtaposition of the subject and a nonverbal predicate. The frequent use of the past participle passive as a verbal equivalent leads to a preference for passive constructions, in a way typical of the Prākrits. Use of the absolutive becomes in the classical language a common means to form complex sentences by indicating actions occurring before that of the main verb; again the effect is a reduction in finite verbal forms. The usual sentence order is subject, object, verb; however, this is so commonly modified for emphasis (with initial and final positions in the sentence or verse-line carrying most emphasis) that Sanskrit word order is often regarded as being free. In vocabulary, the freeing from the affective connotations of a natural language brought a striking enlargement of the range of synonyms, skillfully exploited in much of the classical literature to produce rich sound effects.

In its morphology, Sanskrit is broadly comparable to Greek or Latin, though somewhat more complex. In both the nominal and verbal systems the dual is obligatory for all twos, not just pairs. The nominal system employs eight cases (seven according to the Indian reckoning, which regards the vocative as a form of the stem), three numbers, and three genders (masculine, feminine, neuter). Unlike other Indo–European languages, Sanskrit lacks a developed series of prepositions, and the relatively few adverbial formations used to define case relationships more exactly tend to be placed after the noun. The use of *vṛddhi* (IE strengthened grade) to form derivatives from nominal stems is a notable feature. The verb has two voices, active and middle, their functions well distinguished by the Sanskrit terms for them: *parasmaipada* 'word for another' and *ātmanepada* 'word for oneself'; it also has five moods (injunctive, imperative, subjunctive, optative, and precative) in the Vedic, somewhat simplified in the classical language. Prepositional affixes to the verb may in Vedic be separated from the verb but in the classical language must be prefixed to it (there is a comparable development between Homeric and classical Greek).

There is both an ordinary sigmatic future and a periphrastic future (formed through a specialized use of the agent noun), several aorist formations (principally a sigmatic aorist and a root aorist), and a perfect normally formed with a reduplicated stem; these are comparable to the equivalent tenses in Greek or Latin. The augment is prefixed to several past tenses: imperfect, aorist, pluperfect, and conditional. Verbal roots are divided by the Sanskrit grammarians into 10 classes: six athematic and four thematic. A distinctive feature of the verbal system is the employment of secondary conjugations with specific meanings: causative, intensive, and desiderative. Historically, the passive is also such a secondary conjugation, formed by adding the middle endings to a modified root. The Vedic language is marked by rather greater grammatical complexity with, most notably, a whole range of case forms from nouns functioning as infinitives, which are reduced to a single infinitive in the classical language. It also possessed a pitch accent that had died out by the time of the classical language.

Phonetically Sanskrit is marked by a number of innovations by comparison with other Indo–European languages of comparable age. It is also notable for the concern with phonetics of its own grammarians (exemplified by the fact that the alphabet is arranged according to the organ of articulation, with vowels preceding consonants) and the precision of their descriptions. On the one hand, Sanskrit has collapsed the three Indo–European vowels *a, e*, and *o* into *a*, and on the other it has introduced a complete new class of consonants, that of the retroflex consonants, mainly under the influence of one of the other language groups already present in India, either Dravidian or Munda, although in some instances the retroflex consonants probably arose through internal phonetic developments in relation to *ṣ* and *r*. The most widely known feature is that of *saṃdhi* 'junction,' the process of phonetic assimilation of contiguous sounds at the junctures between both words and their component parts (external and internal *saṃdhi*).

Sample Sentence

teṣāṃ	*khalv*	*eṣāṃ*	*bhūṭānāṃ*	*trīṇy*
/teṣa:ŋ	khəlv	eṣa:ŋ	bhu:ta:na:ŋ	tri:ɳy
eva	*bījāni*	*bhavanty*	*aṇḍajaṃ*	
evə	bi:ja:ni	bhəvənty	əɳɖəjəŋ	
jīvajam	*udbhijjam*	*iti*‖		
ji:vəjəm	udbhijəŋ	iti/		

'Living beings here have just three origins [literally 'Assuredly of these living beings are/come into being indeed three seeds']: being born from an egg or live-born or produced from a sprout.'

This simple sentence (from *Chāndogya Upaniṣad* 6.3.1) exemplifies several of the features that are taken to extremes in the classical language. There is the avoidance of a transitive construction (although here the verb, *bhavanti*, is expressed, whereas later such a copula is normally suppressed), the employment of compounds, and the liking for etymological figures (the latter two combined in the three compounds ending in the adjectival form *-ja*, coming from √*jan* 'to be born,' while the use of cognates is exemplified by *bhavanti* third pl present indicative and *bhūta* past participle passive from √*bhū* 'to become'). The use of *iti* may also be noted – here to function as the equivalent of the colon in the translation, more usually to perform the function of quotation marks, to mark off a passage in direct speech from the sentence in which it is embedded (an idiom probably calqued on the Dravidian); Sanskrit has no method of indicating indirect speech.

Role and Influence in Indian Culture

As is implicit in some of the statements above, it is clear that throughout the main period of its use as a literary language Sanskrit was not the first language of its users, who in North India would have been native speakers of one of the Prākrits deriving from Sanskrit (used here in its widest sense of the group of OIA dialects) or even of the next stage of MIA, the Apabhraṃśas, and in South India were speakers of one of the Dravidian languages (which have been influenced to varying degrees in their vocabulary by Sanskrit). The prestige attaching to its use for the Vedas, the authoritative scriptures for Hindus, resulted in its being regarded as the only language fit for use in the major rituals of brahmanical Hinduism, a role that to a limited extent it retains to this day. This was undoubtedly the reason why the Purāṇas and the many popular texts related to them were composed (from the fourth century to as late as the nineteenth century) in a form of Sanskrit that is greatly indebted to the epics for its linguistic and metrical expression, while similarly Mahāyāna Buddhism employed the so-called Buddhist Hybrid Sanskrit (essentially a Sanskritization of MIA). Sanskrit has therefore been a dominant influence on the development of the languages in both the MIA and NIA phases, supplying much of the religious vocabulary in the form of direct loans, over and above the large proportion of the vocabulary descended from Sanskrit.

Sanskrit and the West

First acquaintance with Sanskrit by Western scholars came even before the period of British rule. Sir William

Jones's famous discourse in 1786 to the Asiatick Society in Calcutta on the affinity of Sanskrit with Greek, Latin, and the other languages now known as Indo–European was not the first notice of such connection, which had been proposed two centuries earlier by Thomas Stevens (in 1583) and Fillipo Sassetti (in 1585). However, Jones's eminence ensured it a much wider audience than before, and this was in a significant sense the start of the discipline of comparative philology, whereas the appreciation before long of the achievements of the early Indian grammarians was an important stimulant to the development of modern linguistics, which has paid them the compliment of borrowing a number of their terms, such as *saṃdhi*.

Pioneers: Missionaries and Travelers in India (1583–1768)

The first known observation of a similarity between Indian and Western languages occurred in a letter of 1583 (published 1957) by Jesuit missionary Thomas Stephens/Stevens, which does not mention Sanskrit, but Indian vernaculars and Greek and Latin. A letter of 1586 (published 1855) by litterateur-merchant Filippo Sassetti noted Sanskrit's status as India's learned language, its antiquity and complexity, and lexical similarities with Italian, notably in numerals 6–9 and words for 'god' and 'snake.' In 1660–1662, Jesuit Heinrich Roth wrote, in Latin, the first European grammar of Sanskrit (published 1988); though organized on a Western plan, it follows Indian terminology and analysis.

In a letter of 1725 (published 1729), Protestant missionary Benjamin Schul(t)ze listed Sanskrit numerals with equivalents in Latin for all, and in other European languages for some. He offered in the *Orientalisch- und Occidentalischer Sprachmeister* (1748) a Sanskrit translation of the Lord's Prayer, reproduced in Adelung's *Mithridates* (1806). Most influential was a survey of Sanskrit literature (1740; published 1743) by Jesuit Jean-François Pons, which described Sanskrit as "admirable for its harmony, copiousness, and energy" and reported on the analysis by which native grammarians reduced "the richest language in the world" to a small number of primitive elements to which derivational suffixes and inflectional endings are added, according to rules the application of which generates "several thousand correct Sanskrit words." It informed the works of de Brosses, Dow, Sinner, Voltaire, Monboddo, Halhed, Beauzée, and Hervas, and was plagiarized by John Cleland (1778). In 1732–1733, Pons sent to the French Royal Library 168 Sanskrit manuscripts, which included the first five chapters of a grammar in Latin with Sanskrit words in Bengali script. A sixth chapter on syntax, in French with Sanskrit words partly in Telugu, partly in Roman script, was forwarded in 1772 by Gaston-Laurent Coeurdoux. Pons's grammar, which Anquetil-Duperron came close to publishing in 1804, was the first primer for students of Sanskrit in Europe. Coeurdoux was the author of a memoir that included, besides a basic vocabulary, lists of Sanskrit words that have equivalents in Latin, Greek, or both, notably numerals, pronouns, and a partial paradigm of *as-* 'to be.' Solicited in 1767 by the Académie des Inscriptions et Belles-Lettres, it was read only in 1786 and published in 1808, the same year as Friedrich Schlegel's *Ueber die Sprache and Weisheit der Indier*, which rendered it obsolete.

These pioneers' sometimes faulty data – muddled by erratic transliterations that reflected different local pronunciations and the recorders' various native tongues, and subject to misreading – were interpreted according to, or used to bolster divergent linguistic theories. Gottfried Siegfried Bayer (1738) explained similarities by contact and borrowing, yet a memoir of the Tranquebar missionary Christian Theodor Walther (1733), which Bayer appended, attributed them to the common Scythian origin propounded by Boxhorn, Saumaise, Jager, Leibniz, and others.

Jones's famous discourse in 1786 to the Asiatick Society in Calcutta on the affinity of Sanskrit with Greek, Latin, and the other languages now known as Indo–European was not the first notice of such connection, which had been proposed two centuries earlier by Thomas Stevens (in 1583) and Fillipo Sassetti (in 1585). Pioneers: Missionaries and Travelers in India (1583–1768)

The first known observation of a similarity between Indian and Western languages occurred in a letter of 1583 (published 1957) by Jesuit missionary Thomas Stephens/Stevens, which does not mention Sanskrit, but Indian vernaculars and Greek and Latin. A letter of 1586 (published 1855) by litterateur-merchant Filippo Sassetti noted Sanskrit's status as India's learned language, its antiquity and complexity, and lexical similarities with Italian, notably in numerals 6–9 and words for 'god' and 'snake.' In 1660–1662, Jesuit Heinrich Roth wrote, in Latin, the first European grammar of Sanskrit (published 1988); though organized on a Western plan, it follows Indian terminology and analysis.

In a letter of 1725 (published 1729), Protestant missionary Benjamin Schul(t)ze listed Sanskrit numerals with equivalents in Latin for all, and in other European languages for some. He offered in the *Orientalisch- und Occidentalischer Sprachmeister* (1748) a Sanskrit translation of the Lord's Prayer, reproduced in Adelung's *Mithridates* (1806). Most influential was a survey of Sanskrit literature (1740; published 1743) by Jesuit Jean-François Pons, which described Sanskrit as "admirable for its harmony, copiousness, and energy" and reported on the analysis by which native grammarians reduced "the richest language in the world" to a small number of primitive elements to which derivational suffixes and inflectional endings are added, according to rules the application of which generates "several thousand correct Sanskrit words." It informed the works of de Brosses, Dow, Sinner, Voltaire, Monboddo, Halhed, Beauzée, and Hervas, and was plagiarized by John Cleland (1778). In 1732–1733, Pons sent to the French Royal Library 168 Sanskrit manuscripts, which included the first five chapters of a grammar in Latin with Sanskrit words in Bengali script. A sixth chapter on syntax, in French with Sanskrit words partly in Telugu, partly in Roman script, was forwarded in 1772 by Gaston-Laurent Coeurdoux. Pons's grammar, which Anquetil-Duperron came close to publishing in 1804, was the first primer for students of Sanskrit in Europe. Coeurdoux was the author of a memoir that included, besides a basic vocabulary, lists of Sanskrit words that have equivalents in Latin, Greek, or both, notably numerals, pronouns, and a partial paradigm of *as-* 'to be.' Solicited in 1767 by the Académie des Inscriptions et Belles-Lettres, it was read only in 1786 and published in 1808, the same year as Friedrich Schlegel's *Ueber die Sprache and Weisheit der Indier*, which rendered it obsolete.

These pioneers' sometimes faulty data – muddled by erratic transliterations that reflected different local pronunciations and the recorders' various native tongues, and subject to misreading – were interpreted according to, or used to bolster divergent linguistic theories. Gottfried Siegfried Bayer (1738) explained similarities by contact and borrowing, yet a memoir of the Tranquebar missionary Christian Theodor Walther (1733), which Bayer appended, attributed them to the common Scythian origin propounded by Boxhorn, Saumaise, Jager, Leibniz, and others.

La Flotte (1768) also posited a 'North Asian' origin, while Sinner (1771) thought of borrowing from Greek and Latin. The emphasis on numerals and other basic vocabulary, i.e., vocabulary unlikely to have been borrowed, which De Laet, Grotius, Leibniz, and others pioneered, did not necessarily lead to the conclusion of a common origin. Schul(t)ze credited similarities between Latin and Sanskrit to borrowing from Portuguese, while Coeurdoux favored the biblical myth of Babel, making of Sanskrit one of the primitive languages that preserved elements that antedated separation. Evidence from Sanskrit fed individual theories from the 'language mechanics' of de Brosses (1765), fascinated by Pons's report of Sanskrit's derivation from a handful of primitive elements, to the Celtomania of Le Brigant (1767).

Breakthrough: Colonials in Bengal (1768–1788)

Sanskrit's reputation for being "amazingly copious" and for showing a "regularity of etymology and grammatical order" induced Alexander Dow (1768) to suspect that Brahmans invented it "upon rational principles" to be "a mysterious repository for their religion and philosophy." This assumption led Christoph Meiners (1780) to explain similarities by assuming that the Brahmans patterned Sanskrit after Greek, a notion Dugald Stewart and Charles William Wall still held in the 19th century.

Governor Warren Hastings' orientalist policies and patronage of both pandits and orientalists caused a breakthrough. In the introduction to the translation of the *Code of Gentoo Laws* (1776) that Hastings commissioned, Nathaniel Brassey Halhed gave an account of Sanskrit that interested Beauzée and Monboddo among others. In his grammar of Bengali (1778), Halhed digressed on features of Sanskrit, spelling out the importance of similarities not only in basic vocabulary, but for the first time also in morphology, such as the conjugation in *-mi* in Sanskrit and Greek. In an unpublished letter of 1779, he articulated a method, built on Monboddo's view that Latin was a dialect more ancient than Greek: Sanskrit, closer to Latin than to Greek, had to be even more ancient, yet what of "the existence of the dual number and the middle voice in this tongue and in the Greek, which are totally absent from the Latin"? Holding, after Monboddo, that "it is one of the last gradations of art to simplify a complex machine," he mentioned "in favour of the pretensions to priority of original in the Shanscrit language, that it contains every part of speech, and every distinction which is to be found in Greek or in Latin, and that in some particulars it is more copious than either."

Sanskrit's 'copiousness' was emphasized again in Sir William Jones's statement of 1786 (published 1788), which, taken out of context, was elevated later to the rank of a charter of comparative Indo-European linguistics:

> The Sanskrit language, whatever be its antiquity, is of a wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could possibly have been produced by accident; so strong indeed, that no philologer could examine them all three, without believing them to have sprung from some common source, which, perhaps, no longer exists: there is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a very different idiom, had the same origin with the Sanskrit; and that the old Persian might be added to the same family.

For Jones, in keeping with the monogeneticism of his times, this emphasis was part of a search for a cradle of civilization, which encompassed also Egyptians, Ethiopians, Chinese, Japanese, even Peruvians. Yet it informed Michael Hissmann's summary of the evidence from Pons, Dow, and Halhed, interpreted to favor borrowing into Sanskrit (1780), and sidelined Beauzée's attempt to make of Sanskrit a model for an international scholarly language (1786). By founding the Asiatic Society in Calcutta (1784) and its organ, the *Asiatick Researches* (1788–), Jones provided a forum for further advances and a channel to broadcast them to Europe.

Taking Stock in Europe (1788–1802)

Returned missionary Paulinus a Sancto Bartholomaeo undertook to catalog oriental collections in Rome and to publish encyclopedic, if polemical, works that included the first two grammars of Sanskrit to be printed (1790, 1804), based on now lost manuscripts by Hanxleden; an edition of the first section of Amarasiṃha's dictionary (1798); and dissertations on the relationship of Zend, Sanskrit, and German, and of Latin, Zend, and Sanskrit (1798, 1802). He continued to emphasize basic vocabulary presented in tabular form for comparison, but discarded explanations by contact and borrowing. He rejected a Scythian origin in favor of an oriental cradle and judged Sanskrit to be closer to Latin than to Greek, while acknowledging that morphological similarities, such as the augment and the reduplicated perfect, point otherwise. Franz Carl Alter (1799) published the Sanskrit words in the St. Petersburg vocabularies corrected by Paulinus, and Paulinus's and his own comparisons of these with other oriental

languages. Hervas (1801) and Adelung (1806) drew heavily on Paulinus's work.

A New Beginning: Sanskrit in Paris (1802–1808)

In 1802, the oriental collections in the French National Library attracted the Scot Alexander Hamilton, a returned member of Jones's Asiatic Society, who cataloged anew the Sanskrit manuscripts with their keeper, Louis-Matthieu Langlès (1807), and introduced interested scholars to Sanskrit. Of the first consequence was his tutoring of Friedrich Schlegel, which provided a foundation for Schlegel's *Ueber die Sprache und Weisheit der Indier* (1808). In this complex and sometimes paradoxical book, Schlegel retreated from the first enthusiasm that had him exclaim that Sanskrit is "the actual source of all languages, of all thoughts and poetry of the human spirit; everything, everything without exception stems from India." Yet he still viewed Sanskrit as the most perfect, spiritual, quasi-divine language, the oldest, and possibly the parent of 'organic,' inflectional languages, which he considered superior to the 'mechanical,' agglutinative languages. Deeming lexical similarities inherently inconclusive, he focused on morphological similarities as the determining criterion for establishing genealogy.

Mainstream (1808–)

Schlegel's example showed that Sanskrit could be learned in Europe. It inspired Antoine-Léonard de Chézy, who, self-taught with the grammars of Paulinus and Pons and other manuscripts, became in 1814 the first incumbent of a chair of Sanskrit, at the Collège de France. August Wilhelm Schlegel followed in the footsteps of his younger brother, learning Sanskrit in Paris before initiating its teaching in Germany, in Bonn (1818). Franz Bopp, Othmar Frank, and others went on from Paris to London to consult manuscripts in the East India Company Library, which housed the great collections of Colin Mackenzie and of Henry Thomas Colebrooke, the first author of a Sanskrit grammar in English (1805), which remained incomplete, and the first Sanskrit scholar, some of whose works are still read for other than historical interest. Hamilton taught Sanskrit at the college opened in 1806 to train the civil servants of the East India Company, but no British university offered Sanskrit until 1832, when the Boden chair was created at Oxford in belated fulfillment of a bequest by a military officer of the East India Company. The qualifications of this chair's first incumbent, Horace Hayman Wilson, who learned Sanskrit from pandits in India, were challenged by A. W. Schlegel, who learned Sanskrit in Europe, in a public dispute that epitomized the appropriation of Sanskrit by Europeans, particularly on the Continent.

Sanskrit took pride of place in the development of comparative Indo-European grammar. Unlike Friedrich Schlegel, Bopp never referred to Sanskrit as the parent language, but he made it the centerpiece of his comparative studies of conjugational and other grammatical systems. Sanskritocentrism remained the norm for generations of comparatists. So significant was the discovery of Sanskrit in the development of comparative Indo-European linguistics that it has been felt necessary to voice reminders that it was not a prerequisite – as the works of Rask, Grimm, and others demonstrate. Accounting in part for the magnitude of this impact are the quality, quantity, antiquity, and longevity of Sanskrit literature, yet more important was the fact that Sanskrit was first taught to Europeans – directly or mediately – according to the tradition of rigorous analysis by Pāṇini and other Indian grammarians and phoneticians. The identification of the root as the smallest common denominator of derived forms, vocalic alternation, derivational and inflectional suffixes, substitution rules, zeroing, etc., and the description of articulatory processes were the procedures according to which Europeans learned Sanskrit from pandits. While this method of learning created an illusion that Sanskrit is more regular and transparent than other languages, the fact that the same procedures could serve to analyze cognate languages provided a framework for comparison.

Santali

G D S Anderson, Max Planck Institute, Leipzig, Germany, and University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Santali (*hɔ̣r rɔ̣r*), a member of the North Munda (Kherwarian) subgroup of the Munda family within the Austroasiatic linguistic phylum, is spoken by between 5 million and 7 million people across several states in eastern and central India. The most compact area of Santal settlement is in the Sadar subdivision of Bunkura, the Jhargram subdivision of Midnapur, and Purulia in West Bengal; south of Bhagalpur and Monghyr, in the Santal Parganas, Hazaribagh and Dhalbhum in Bihar, and the newly formed tribal-dominant state of Jharkhand; and Baleshwar, Mayurbhanj, and Keonjhar in Orissa. In Bangladesh, the Santals are found mainly in Rajsahi, Rangpur, and the Chittagong Hill tracts (Ghosh, 1994: 3).

Santali is characterized by a split into at least a northern and southern dialect sphere, with slightly different sets of phonemes (Southern Santali has six phonemic vowels, in contrast with eight or nine in Northern Santali), different lexical items, and to a certain degree, variable morphology as well (e.g., the-*ič*':-*rɛ*n singular:plural opposition in animate genitive case markers).

There is a degree of laryngeal tension (phonation type) associated with certain Santali vowels. This gives Santali and the closely related Mundari their characteristic sound and differentiates these two languages from other languages of the region. Instrumental studies are needed to determine the exact phonetic characteristics of this. In addition, a wide range of vowel combinations may be found in Santali; this tendency finds an extreme expression in words such as *kɔeaeae* 'he will ask for him'.

The following statements can be made regarding the consonantism of Santali: retroflexion, while attested, is less developed in Santali (and Munda) generally than in Indo-Aryan or Dravidian languages. Further, in coda position, there is a characteristic use of so-called checked consonants, ranging in articulation from preglottalized to unreleased. Examples of checked consonants in final position in Santali include *sɛč* 'towards', *rit'* 'grind', *selep'* 'antelope', and *dak'* 'water' (Bodding, 1923: 79); before vowels (generally speaking), these consonants alternate with voiced stops, as in *dal-aka-'t-ko-a-e* 'he has beat them' vs. *dal-aka-d-e-a-e* 'he has beaten him'. Santali also makes use of prenasalized stops in a number of words as well: *kʰokṇḍo* 'ill conditioned', *məñjʰlə* 'fourth of six brothers', *mɔ̃ñj* 'beautiful', *oṭʰŋgao*'to steady on', *gaṇḍke* 'log', *oṇḍga* 'ogre', *bʰosṇḍo*'slovenly', *beṃbak'* 'incorrectly', and *telŋga* 'stick'; also *kʰəṃduŋ* ~ *kʰəṃduŋ* 'deep', *kɔṃ̃jɛ* (~*kɔñjɛ*) 'crooked', and *dʰaṛŋga* (~*dhəŋgra/i*) 'strapping' (Bodding, 1923: 36ff.).

Santali has a complicated demonstrative system (Zide, 1972). Its basic three-way system is a straightforward proximal, distal, remote system in animate (-*i*/*kin*/*ko*) and inanimate forms (-*a*/-*akin*/-*ako*), as shown in the following examples (ANIM, animate; INAN, inanimate; SG, singular; DL, dual; PL, plural):

(1a) Proximal:

	SG	DL	PL
ANIM:	nui	nukin	noko/nuku
INAN:	noa	noakin	noako
	'this'	'these 2'	'these'

Santali

G D S Anderson, Max Planck Institute, Leipzig, Germany, and University of Oregon, Eugene, OR, USA

© 2006 Elsevier Ltd. All rights reserved.

Santali (*hɔ̣r rɔ̣r*), a member of the North Munda (Kherwarian) subgroup of the Munda family within the Austroasiatic linguistic phylum, is spoken by between 5 million and 7 million people across several states in eastern and central India. The most compact area of Santal settlement is in the Sadar subdivision of Bunkura, the Jhargram subdivision of Midnapur, and Purulia in West Bengal; south of Bhagalpur and Monghyr, in the Santal Parganas, Hazaribagh and Dhalbhum in Bihar, and the newly formed tribal-dominant state of Jharkhand; and Baleshwar, Mayurbhanj, and Keonjhar in Orissa. In Bangladesh, the Santals are found mainly in Rajsahi, Rangpur, and the Chittagong Hill tracts (Ghosh, 1994: 3).

Santali is characterized by a split into at least a northern and southern dialect sphere, with slightly different sets of phonemes (Southern Santali has six phonemic vowels, in contrast with eight or nine in Northern Santali), different lexical items, and to a certain degree, variable morphology as well (e.g., the-*ič*':-*rɛ*n singular:plural opposition in animate genitive case markers).

There is a degree of laryngeal tension (phonation type) associated with certain Santali vowels. This gives Santali and the closely related Mundari their characteristic sound and differentiates these two languages from other languages of the region. Instrumental studies are needed to determine the exact phonetic characteristics of this. In addition, a wide range of vowel combinations may be found in Santali; this tendency finds an extreme expression in words such as *kɔeaeae* 'he will ask for him'.

The following statements can be made regarding the consonantism of Santali: retroflexion, while attested, is less developed in Santali (and Munda) generally than in Indo-Aryan or Dravidian languages. Further, in coda position, there is a characteristic use of so-called checked consonants, ranging in articulation from preglottalized to unreleased. Examples of checked consonants in final position in Santali include *sɛč* 'towards', *rit'* 'grind', *selep'* 'antelope', and *dak'* 'water' (Bodding, 1923: 79); before vowels (generally speaking), these consonants alternate with voiced stops, as in *dal-aka-'t-ko-a-e* 'he has beat them' vs. *dal-aka-d-e-a-e* 'he has beaten him'. Santali also makes use of prenasalized stops in a number of words as well: *kʰokṇḍo* 'ill conditioned', *məñjʰlə* 'fourth of six brothers', *mɔ̃ñj* 'beautiful', *oṭʰŋgao*'to steady on', *gaṇḍke* 'log', *oṇḍga* 'ogre', *bʰosṇḍo*'slovenly', *beṃbak'* 'incorrectly', and *telŋga* 'stick'; also *kʰəṃduŋ* ~ *kʰəṃduŋ* 'deep', *kɔṃ̃jɛ* (~*kɔñjɛ*) 'crooked', and *dʰaṛŋga* (~*dhəŋgra/i*) 'strapping' (Bodding, 1923: 36ff.).

Santali has a complicated demonstrative system (Zide, 1972). Its basic three-way system is a straightforward proximal, distal, remote system in animate (-*i*/*kin*/*ko*) and inanimate forms (-*a*/-*akin*/-*ako*), as shown in the following examples (ANIM, animate; INAN, inanimate; SG, singular; DL, dual; PL, plural):

(1a) Proximal:

	SG	DL	PL
ANIM:	nui	nukin	noko/nuku
INAN:	noa	noakin	noako
	'this'	'these 2'	'these'

(1b) Distal:

	SG	DL	PL
ANIM:	uni	unkin	onko/unku
INAN:	ona	onakin	onako
	'that'	'those 2'	'those'

(1c) Remote:

	SG	DL	PL
ANIM:	hani	hankin	hanko
INAN:	hana	hanakin	hanako
	'that yonder'	'those (2) yonder'	

Alongside these are intensive forms (Example (2); marked by infixation of *-k'-*), 'just' forms (Examples (3a) and (3b); marked by a shift of (*o*/*u*>)-*i*-), as well as forms adding connotations of 'things seen' and 'things heard' (Examples (4a)–(4c)):

(2) Intensives:
nuk'ui 'this very one'
nik'i 'just this very one'
nɔk'ɔy 'this very thing'

(3a) 'Just' proximal:

	SG	DL	PL
ANIM:	nii	nikin	neko/niku
INAN:	nia	niakin	niako
	'just this'	'just these 2'	'just these'

(3b) 'Just' distal:

	SG	DL	PL
ANIM:	ini	inkin	enko/inku
INAN:	ina	inakin	inako
	'just that'	'just those (2)'	

(4a) 'Seen' distal:

SG	DL	PL
ɔnɛ	ɔnɛkin	ɔnɛko
'that seen'	'those (2) seen'	

(4b) 'Seen' remote:

SG	DL	PL
hanɛ	hanɛkin	hanɛko
'that yonder seen'	'those (2) yonder seen'	

(4c) 'Heard' distal:

SG	DL	PL
ɔtɛ	ɔtɛkin	ɔtɛko
'that heard'	'those (2) heard'	

Verbs as a lexical category in Santali, and indeed in Munda languages generally speaking, are not easily or rigorously defined in opposition to nouns (Bhat, 1997; Bhattacharya, 1975; Cust, 1878; Pinnow, 1966). As seen in the following examples (Ghosh, 1994: 21), one and the same root may be used as a noun, as a modifier (adjective/participle), and as a predicate/verb. Even a noun root such as 'house' may be used verbally with verbal inflection (ASP, aspect; TR, transitive; FIN, finite):

(5a) kombro kombro mɛrɔm
thief stolen goat
'thief' 'a stolen goat'

(5b) mɛrɔm-ko kombro-ke-d-e-a
goat-PL steal-ASP-TR-3-FIN
'They stole the goat'.

(5c) oṛak-ke-d-a-e
house-ASP-TR-FIN-3
'He made a house'.

The default position for subject agreement clitics is in immediately preverbal position in Santali. Note in the following examples (Bodding, 1929a: 58, 60, 208) that this is true even if the element appearing in this position is an overt subject (or object) pronoun (1, first person; INTR, intransitive; 2, second person; LOC, locative; ALL, allative):

(6a) Kumbṛəbad-te-ko əgu-ke-'t-le-a
K-LOC/ALL-PL bring-ASP-TR–1PL-FIN
'They brought us to Kumbrabad'.

(6b) hẽ iñ-iñ cala'k-a
yes I–1 go.INTR-FIN
'Yes I will go'.

(6c) iñ am-iñ ñɛl-mɛ-a
I you-1 see-2-FIN
'I will see you'.

A wide range of arguments or referents may be encoded within the Santali verbal complex. This includes subjects, direct objects, indirect objects, benefactives, and possessors of subjects or objects. Note that Santali is doubly unusual in its system of possessor indexing: it takes a special series of possessive inflection, and this pattern of referent indexing does not reflect a process of 'raising' (to argument/term status of this logical modifier/operator), as a verb in Santali may encode both its logical argument and a possessor of that argument simultaneously, as in Example 7d). Examples (7a)–(7d) are from Bodding (1929a: 212, 1923: 22, 21–22, 209), respectively, and Example (7e) is from Ghosh (1994: 65) (NEG, negation; ANT, anterior; BEN, benefactive; POSS, possessor):

(7a) ba-ko sap'-le-d-e-a
NEG-PL catch-ANT-TR-3-FIN
'They did not catch him'.

(7b) im-əñ-me
give-1-2
'give me'

(7c) dul-a-ñ-me
pour.out-BEN-1-2
'Pour out for me'.

(7d) sukri-ko gɔ'c-ke-d-e-tiñ-a
pig-PL die-ASP-TR-3-1.POSS-FIN
'They killed my pig'.

(7e) hɔpɔn-e hɛč'-en-tiñ-a
son-3 come-PAST.INTR-1.POSS-FIN
'My son came'.

The Santali language has been written in at least five alphabets, depending on the locale of production

and the purpose of the written material. There have been Santali publications in Devanagari (Hindi), Oriya, Bengali, and Roman and in the *ɔl čɛmɛt'* ~ *ɔl čiki* script of indigenous origin (Zide, 2000: 8). An ever-growing body of literature has appeared in Santali, and the language is used on a limited basis in other media (e.g., shortwave radio broadcasts).

São Tomé and Príncipe: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Africa's smallest country consists of two islands in the Gulf of Guinea, facing Gabon. The bigger island of the two, São Tomé, is the center of commercial and administrative activity, and it is where the capital, also called São Tomé, is found. The smaller island of Príncipe gained limited autonomy in 1995. The population of São Tomé and Príncipe is about 181 000 (2004 estimate).

São Tomé and Príncipe was under Portuguese control from the 15th century up to independence in 1975. The Portuguese colonizers used the islands as a port in the slave trade, as well as for large-scale, slave-based plantations growing sugar cane and later cocoa. A large number of the population of São Tomé

and the purpose of the written material. There have been Santali publications in Devanagari (Hindi), Oriya, Bengali, and Roman and in the *ɔl čɛmɛt'* ~ *ɔl čiki* script of indigenous origin (Zide, 2000: 8). An ever-growing body of literature has appeared in Santali, and the language is used on a limited basis in other media (e.g., shortwave radio broadcasts).

São Tomé and Príncipe: Language Situation

Editorial Team

© 2006 Elsevier Ltd. All rights reserved.

Africa's smallest country consists of two islands in the Gulf of Guinea, facing Gabon. The bigger island of the two, São Tomé, is the center of commercial and administrative activity, and it is where the capital, also called São Tomé, is found. The smaller island of Príncipe gained limited autonomy in 1995. The population of São Tomé and Príncipe is about 181 000 (2004 estimate).

São Tomé and Príncipe was under Portuguese control from the 15th century up to independence in 1975. The Portuguese colonizers used the islands as a port in the slave trade, as well as for large-scale, slave-based plantations growing sugar cane and later cocoa. A large number of the population of São Tomé

and Príncipe thus has historic roots in the former Portuguese colonies of Angola, Mozambique, and Cape Verde Islands.

Through the mix of speakers of different African languages, different creole languages developed, with Bantu and Kwa substrate and largely Portuguese-based lexicons. The two main creoles on São Tomé are Sãotomese and Angolar. Sãotomense has the larger number of speakers and is spoken throughout the greater part of the island. Angolar is spoken in smaller pockets in the south, west, and east of the island and shows greater lexical influence from Angolan Bantu languages (notably Kimbundu (Mbundu, Loanda)) than does Sãotomese. Sãotomese is the national language of São Tomé. The main creole language of Príncipe is Principense. Despite being the national language of the island, Principense has only a few speakers, so the status as national language has a mostly symbolic function. The creole languages of São Tomé and Príncipe are historically and structurally similar to Fa D'Ambu, the creole language of Annobón Island of Equatorial Guinea.

In addition to Sãotomese, Angolar, and Principense, Portuguese is used widely, especially outside of informal contexts.

Sapir, Edward (1884–1939)

J G Fought, Pomona College, Claremont, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Edward Sapir was born in Lauenberg, Pomerania. His family immigrated to the United States in 1889. He received his higher education at Columbia University, earning his B.A. in 1904, an M.A. in Germanic languages the next year, and completing his Ph.D. in anthropology in 1909, along with some advanced studies in historical and comparative linguistics.

He was first exposed to Native American languages as a graduate student under the direction of Franz Boas. The new approach to anthropology developed (and largely administered) by Boas integrated the study of cultures and their languages, as both were manifested in the content and form of traditional texts. Few would dispute that Sapir was unequalled among American anthropologists of his generation. Between 1907 and 1910 he held research fellowships at the University of California and the University of Pennsylvania. From 1910 to 1925, he was in charge of the new Division of Anthropology of the Geological Survey of Canada, based in Ottawa, enabling him to sponsor field studies by himself and others.

Sapir's intense, far-reaching field work began in 1905, with an Wasco-Wishram Chinookan, and over the next five years alone he covered six other languages, including his landmark description of Takelma (completed in 1911, and published in 1922) making him the paragon of Boasian, linguistically driven anthropology. Sapir's extraordinary energy and phonetic skills were the foundation for his capacity for quickly, accurately, and insightfully compiling and analyzing vast amounts of textual and grammatical data from a wide range of American languages. Unlike his contemporary Leonard Bloomfield, whose informant sessions were carefully nondirective, Sapir drew in and mobilized his informants, training them to write accurately in their own languages and to compile and translate traditional texts, which he then worked through with them. Early in their careers, the descriptive writings—the linguistics—of Sapir and Bloomfield seemed more alike in method than their later works. These apparent differences owe something to their very different personalities and their divergent rhetorical styles. It seems likely also that Sapir's wider anthropological responsibilities played a role. That each understood and respected the other's work can be seen in Sapir (1931) and Bloomfield (1922).

Sapir's training in historical and comparative linguistics prepared him to exploit the growing body of data from American languages as a means of dating cultural contacts and migrations through linguistic evidence. In his extremely important monograph on

Edward Sapir was born in Lauenberg, Pomerania. His family immigrated to the United States in 1889. He received his higher education at Columbia University, earning his B.A. in 1904, an M.A. in Germanic languages the next year, and completing his Ph.D. in anthropology in 1909, along with some advanced studies in historical and comparative linguistics.

He was first exposed to Native American languages as a graduate student under the direction of Franz Boas. The new approach to anthropology developed (and largely administered) by Boas integrated the study of cultures and their languages, as both were manifested in the content and form of traditional texts. Few would dispute that Sapir was unequalled among American anthropologists of his generation. Between 1907 and 1910 he held research fellowships at the University of California and the University of Pennsylvania. From 1910 to 1925, he was in charge of the new Division of Anthropology of the Geological Survey of Canada, based in Ottawa, enabling him to sponsor field studies by himself and others.

Sapir's intense, far-reaching field work began in 1905, with an Wasco-Wishram Chinookan, and over the next five years alone he covered six other languages, including his landmark description of Takelma (completed in 1911, and published in 1922) making him the paragon of Boasian, linguistically driven anthropology. Sapir's extraordinary energy and phonetic skills were the foundation for his capacity for quickly, accurately, and insightfully compiling and analyzing vast amounts of textual and grammatical data from a wide range of American languages. Unlike his contemporary Leonard Bloomfield, whose informant sessions were carefully nondirective, Sapir drew in and mobilized his informants, training them to write accurately in their own languages and to compile and translate traditional texts, which he then worked through with them. Early in their careers, the descriptive writings—the linguistics—of Sapir and Bloomfield seemed more alike in method than their later works. These apparent differences owe something to their very different personalities and their divergent rhetorical styles. It seems likely also that Sapir's wider anthropological responsibilities played a role. That each understood and respected the other's work can be seen in Sapir (1931) and Bloomfield (1922).

Sapir's training in historical and comparative linguistics prepared him to exploit the growing body of data from American languages as a means of dating cultural contacts and migrations through linguistic evidence. In his extremely important monograph on

Time perspective (1916; reprinted in Mandelbaum, 1949) he recast the older Powell classification of language relationships produced by the Bureau of American Ethnology, which recognized 55 separate stocks. Sapir reduced these to six, in a bold reclassification that is still an active topic of discussion.

In 1925 Sapir accepted an appointment to the University of Chicago. The position opened up new interdisciplinary connections for him: there were linkages with distinguished colleagues in sociology, psychology, and political science. Sapir moved again, to Yale, in 1931. During this period, he worked extensively in culture and personality studies, a field he was instrumental in launching. One of his students at Yale was Benjamin Lee Whorf, whose name is linked with his in connection with a characteristically intuitive hypothesis concerning the mutual influence of habitual forms and patterns in language and culture.

Mandelbaum (1949) presented a selected cross-section of Sapir's important linguistic and anthropological publications. This collection prompted Zellig Harris (1951) to give Sapir's linguistics and its role in the development of the field a long, insightful review. Sapir's collected works, to appear in 16 large volumes, are even now only half published. Native American language texts, grammars, and related linguistic anthropology amount to more than half of this material, an imposing monument to his genius, his energy, and his mastery of the arts of phonetic transcription and morphological analysis. His skill in addressing the public can be enjoyed in his popular book *Language* (1921), which is still in print, still gives the clearest, most accessible picture of a linguist's work, and still attracts new readers to the field.

Saudi Arabia: Language Situation

B Ingham, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The official language is Classical Arabic (Standard Arabic), which is the form used in writing and for official spoken purposes. This preserves the spoken form of the 7th century AD as exemplified by the Quran and pre-Islamic poetry. A diglossic situation exists with colloquial Arabic as the spoken medium in less formal situations.

There is considerable dialect diversity, the main dialect groupings originating in old population centers based on the availability of water for agriculture. These are the following:

1. the Southwestern dialects, including those of Najrān and 'Aṣīr on the borders of Yemen and the émigré 'Ijmān and Āl Murrah bedouin of the east;
2. the urban Ḥijāzi dialects, which are the result of a mixture of Arabian features and those of immigrants from other Arab countries;
3. the Najdi group, including Central and Northern Najd (Jabal Shammar) and the surrounding bedouin dialects, dividing into central and northern Najdi types, which have spread also into Syria and Iraq;
4. the Eastern dialects of the oases of al-Ḥasa.

Possibly because of their isolated location, some dialects of Saudi Arabia have retained many archaic

Saudi Arabia: Language Situation

B Ingham, University of London, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The official language is Classical Arabic (Standard Arabic), which is the form used in writing and for official spoken purposes. This preserves the spoken form of the 7th century AD as exemplified by the Quran and pre-Islamic poetry. A diglossic situation exists with colloquial Arabic as the spoken medium in less formal situations.

There is considerable dialect diversity, the main dialect groupings originating in old population centers based on the availability of water for agriculture. These are the following:

1. the Southwestern dialects, including those of Najrān and 'Aṣīr on the borders of Yemen and the émigré 'Ijmān and Āl Murrah bedouin of the east;
2. the urban Ḥijāzi dialects, which are the result of a mixture of Arabian features and those of immigrants from other Arab countries;
3. the Najdi group, including Central and Northern Najd (Jabal Shammar) and the surrounding bedouin dialects, dividing into central and northern Najdi types, which have spread also into Syria and Iraq;
4. the Eastern dialects of the oases of al-Ḥasa.

Possibly because of their isolated location, some dialects of Saudi Arabia have retained many archaic

features. This gives those of Najd and the bedouins in particular a resemblance to the older historical form of Classical Arabic (Standard Arabic), often remarked upon by earlier travelers and Arabs from outside the region. These features include:

- the retention of the indefinite marker *-in* in nouns, adjectives and participles, as in *wlidin zēn* 'a good boy';
- the retention of the internal passive in verbs in such forms as *gīl* 'it was said,' *yšāf* 'he is seen';
- the presence of certain particles such as *gid* or *ǧid* marking the perfective, *ṯim* or *ṯam* 'there,' and *ilā* or *wilā* 'behold';
- the negative structure *mā bi-* as in *māna b-rāyiḥ* 'I am not going';
- particularly in the southwest, certain lexical forms such as *rēt* 'I saw,' *tēt* 'I came,' and *ḏahabt* 'I went to';
- *lēs-last* 'be not,' cognate with Classical *laysa*, occurring in the dialect of Abha, and a marker *-ū* on nouns in the dialect of Tihāmah cognate with the Classical nominative *-u* ending, though not here acting as a case marker.

Although dialect diversity is wide, the effect of urbanization is producing two standard forms based on the Ḥijāzi and Najdi forms. Amongst the younger elite the influence of the dialects of Greater Syria is also apparent, resulting from education abroad and mixing with other Arab populations. However, the fact that the Najdi ruling class is linked by descent to bedouin populations and that both bedouin and settled Najdi populations have a strong oral literary tradition, often referred to as Nabaṭi poetry, means that the archaic Najdi and particularly bedouin dialects retain considerable prestige.

The dialects of the east particularly have absorbed much English vocabulary through the oil industry.

Saussure, Ferdinand (-Mongin) de (1857–1913)

E F K Koerner, Zentrum für Allgemeine Sprachwissenschaft, Berlin, Germany

© 2006 Elsevier Ltd. All rights reserved.

Saussure (**Figure 1**) was born on November 26, 1857, in Geneva, and died on February 22, 1913, at Château Vufflens near Geneva. He is best known for the posthumous compilation of his lecture notes on general linguistics, the *Cours de linguistique générale*, edited by his former students and first published in 1916 (since translated into more than a dozen languages, including – in order of their first appearance since 1928 – Japanese, German, Russian, Spanish, English, Polish, Italian, Hungarian). However, during his lifetime, Saussure was most widely known for his masterly *Mémoire* of 1879, devoted to an audacious reconstruction of the Proto-Indo–European vowel system. It is generally agreed that his *Cours* ushered in a revolution in linguistic thinking during the 1920s and 1930s, that is still felt today in many quarters, even beyond linguistics proper.

features. This gives those of Najd and the bedouins in particular a resemblance to the older historical form of Classical Arabic (Standard Arabic), often remarked upon by earlier travelers and Arabs from outside the region. These features include:

However, during his lifetime, Saussure was most widely known for his masterly *Mémoire* of 1879, devoted to an audacious reconstruction of the Proto-Indo–European vowel system. It is generally agreed that his *Cours* ushered in a revolution in linguistic thinking during the 1920s and 1930s, that is still felt today in many quarters, even beyond linguistics proper.

Figure 1 Photo of Ferdinand Saussure.

He is universally regarded as 'the father of structuralism.' (For a full bibliography of Saussures writings, see Koerner, 1972a.)

Although from a distinguished Geneva family that – beginning with Horace Bénédict de Saussure, whose portrait adorns the Swiss 20 franc note – can boast of several generations of natural scientists, Ferdinand de Saussure was early drawn to language study, producing an '*Essai pour réduire les mots du grec, du latin et de l'allemand à un petit nombre de racines*' at the age of 14 or 15 (published in *Cahiers Ferdinand de Saussure* [Engler, 1978]). Following his parents' wishes, he attended classes in chemistry, physics, and mathematics at the University of Geneva during 1875–1876, before being allowed to join his slightly older classmates who had left for Leipzig the year before. So in the fall of 1876, Saussure arrived at the university where a number of important works in the field of Indo–European phonology and morphology, including Karl Verner's (*see* **Verner's Law**) epoch-making paper on a series of exceptions to 'Grimm's Law,' had just been published. Saussure took courses with Georg Curtius (*see* **Leskien, August (1840–1916)**), the mentor of the '*Junggrammatiker*,' and a number of the younger professors, such as August Leskien (*see* **Curtius, Georg (1820–1885)**), Ernst Windisch, Heinrich Hübschmann, Hermann Osthoff, and others in the fields of Indic studies, Slavic, Baltic, Celtic, and Germanic. During 1878–1879, Saussure spent two semesters at the University of Berlin, enrolling in courses with Heinrich Zimmer and Hermann Oldenberg. After barely six semesters of formal study, when just 21, he published the major work of his lifetime (Saussure, 1879). In this 300-page work he assumed the existence, on purely theoretical grounds, of an early Proto-Indo–European sound of unknown phonetic value (designated *A) that would develop into various phonemes of the Indo–European vocalic system depending on its combination with various 'sonantal coefficients.' Saussure was thus able to explain a number of puzzling questions of Indo–European ablaut. But the real proof of Saussure's hypotheses came many years later, after his death, following the decipherment of Hittite and its identification as an Indo–European language, and after the Polish scholar Kuryłowicz (*see* **Kuryłowicz, Jerzy (1895–1978)**) in 1927 had pointed to Hittite cognates that contained the sound corresponding to Saussure's *A. These were identified as laryngeals, sounds previously not found in any of the other Indo–European languages.

Having returned to Leipzig, Saussure defended his dissertation on the use of the genitive absolute in Sanskrit in February 1880, leaving for Geneva soon thereafter. Before he arrived in Paris in September of that year, he appears to have conducted fieldwork on Lithuanian, like Schleicher and others before him. In Paris, Saussure found a number of receptive students, among them Antoine Meillet, Maurice Grammont, and Paul Passy, but also congenial colleagues such as Gaston Paris, Louis Havet, who had previously written the most detailed review of his *Mémoire*, and Arsène Darmesteter. Michel Bréal (*see* **Bréal, Michel Jules Alfred (1832–1915)**), the doyen of French linguistics, secured him a position as Maître de Conférences at the École des Hautes Études in 1881, a post he held until his departure for Geneva 10 years later.

During his lifetime, Saussure was best known for his *Mémoire* and the paper on Lithuanian accentuation (1896). Since the 1920s, however, his influence and fame have been almost exclusively connected with the book he never wrote, the *Cours de linguistique générale*. This volume was largely based on notes carefully taken down by a number of his students during a series of lectures on the subject that he had given from 1907 to 1911 at the University of Geneva (to which he had returned as a professor of Sanskrit and Comparative Grammar in 1891). One of them was Albert Riedlinger, whose name appears on the title page of the *Cours*, which was put together by Saussure's successors, Charles Bally and Albert Sechehaye (*see* **Geneva School of Linguistics after Saussure**), neither of whom had attended these lectures themselves (though it is frequently, but erroneously, stated in the literature that they had). The *Cours* was in fact never published in Geneva and was not published in 1915, but in Lausanne and Paris in 1916, that is, exactly 100 years after Franz Bopp's (*see* **Bopp, Franz (1791–1867)**) *Conjugationssystem*, which is usually regarded as the

beginning of comparative–historical Indo–European linguistics.

The ideas advanced in the *Cours* produced a veritable revolution in linguistic science; historical–comparative grammar that had dominated linguistic research since the early 19th century was soon relegated to a mere province of the field. At least in the manner the *Cours* had been presented by the editors, Saussure's general theory of language was seen as assigning pride of place to the nonhistorical, descriptive, and 'structural' approach (Saussure himself did not use the last-mentioned term in a technical sense). This development led to a tremendous body of work concerned with the analysis of the linguistic system of language and its function, and a neglect of questions of language change and linguistic evolution in general – a situation that remains characteristic of the linguistic scene until the 1990s, in particular the framework associated with the name of Noam Chomsky. From the 1920s onwards, a variety of important schools of linguistic thought developed in Europe that can be traced back to proposals made in the *Cours*. These are usually identified with the respective centers from which they emanated, such as Geneva, Prague, Copenhagen, and Paris. In North America too, through the work of Leonard Bloomfield (*see* **Bloomfield, Leonard (1887–1949)**), Saussure's ideas became stock-in-trade among linguists, descriptivists, structuralists, and generativists.

At the core of Saussure's linguistic theory is the assumption that language is a system of interrelated terms which he called 'langue' (in contradistinction to 'parole,' the individual speech act or speaking in general). This 'langue' is the underlying code that ensures that people can speak and understand each other; it has a social underpinning and is an operative system embedded in the brain of everyone who has learned a given language. The analysis of this system, Saussure maintains, is the true object of linguistics. The system is a network of relationships that he characterized as being of two kinds: syntagmatic (i.e., items are arranged in a consecutive, linear order) and associative, later termed 'paradigmatic' (i.e., the organization of units in a deeper fashion dealing with grammatical and semantic relations). Saussure's emphasis on language as 'a system of (arbitrary) signs' and his proposal that linguistics is the central part of an overall science of sign relations or 'sémiologie' have led to the development of a field of inquiry more frequently called 'semiotics' (following C. S. Peirce's terminology), which deals with sign systems in literature and other forms of art, including music and architecture.

Many of the ingredients of Saussure's general theory of language have often been taken out of their original context and incorporated into theories outside of linguistics, at times quite arbitrarily, especially in works by French writers engaged in 'structuralist' anthropology (e.g., Claude Lévi-Strauss, *see* **Levi-Strauss, Claude (b. 1908)**) and philosophy (e.g., Louis Althusser), literary theory (e.g., Jacques Derrida), psychoanalysis (e.g., Jacques Lacan, *see* **Lacan, Jacques (1901–1981)**), and semiotics (e.g., Roland Barthes, *see* **Barthes, Roland (1915–1980)**), and their various associates and followers. The trichotomies (usually reduced to dichotomies) which have become current in 20th-century thought, far beyond their original application, are: *langage-langue-parole* (i.e., language in all its manifestations or 'speech'; language as the underlying system; and 'speaking'), *signe–signifié–signifiant* (sign, signified, and signifier), synchrony versus diachrony ('panchrony' would be a combination of these two perspectives), and syntagmatic versus paradigmatic relations.

Saussure: Theory of the Sign

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The sign theory of Ferdinand de Saussure (1857–1913) is principally to be found in his *Cours de linguistique générale* (*Course in General Linguistics* 1916; translated into English in 1959 and 1983). Saussure's previous work in philology and his focus on the development of Indo-European languages necessarily contains ruminations on the vicissitudes of the linguistic sign but it was his delivery of the course in general linguistics, at short notice to replace a sick colleague, at the University of Geneva from 1907 to 1911, which established his thought in this area. His posthumously published treatise of 1916 was based not on his own writings but on the notes of students present at the course. Specifically, the course was 'reconstructed' for publication by Charles Bally and Albert Sechehaye who stated in their introduction that they were aware of their responsibility to the author who "perhaps might not have authorized the publication of this text" (Saussure, 1983: xx).

The preliminary fact that needs to be taken into account, then, in relation to Saussurean sign theory is that, from the outset, it was never definitive. Readers of the *Cours* cannot be confident that Saussure's exact words are reproduced in full. Furthermore, they cannot be sure that the editorial choices of Bally and Sechehaye were not limited by what was available to them. For example, a notebook of notes in Saussure's hand, unknown to the editors, was discovered in 1996 and may force a re-reading of previous understandings of Saussurean sign theory. More important still, perhaps, is that Saussure's work has been refracted through the work of many illustrious successors beyond the realms of academic linguistics. While Saussure's *Cours* is just one, somewhat fragmented, publication that is still insufficiently read by those dabbling in sign study, the publications and teachings of his successors (or those who have invoked his name) have reached far wider audiences. The latter have had the benefit of an age of media saturation as well as a growing preoccupation with the aspects of communication that lie beyond the objects of linguistics. It is difficult to talk about Saussure's sign theory, then, without mentioning that there is also the Saussurean sign theory of Karcevskij, Vološinov, Jakobson, Benveniste, Hjelmslev, Lévi-Strauss, Lacan, Barthes, Mounin, Chomsky, Derrida, and Baudrillard, to name but a few. (Incisive discussions of a number of these are to be found in Harris, 2003).

Saussure's *Cours* projects "a science *which studies the role of signs as part of social life*" (Saussure, 1983: 15) early in the introduction, but the focus on the linguistic sign appears in Part One on General Principles. From the beginning, Saussure makes it clear that a linguistic sign is not "a link between a thing and a name, but between a concept and a sound pattern" (Saussure, 1983: 66). Moreover, "the sound pattern is not actually a sound; for a sound is something physical" (Saussure, 1983: 66). He therefore stresses that "This sound pattern may be called a 'material' element only in that it is the representation of our sensory impressions" (Saussure, 1983: 66). The linguistic sign is thus a "two-sided psychological entity" (see **Figure 1**).

It should be clear, then, that Saussure is not pursuing the relation between a thing in the world and the

Figure 1 The linguistic sign as a ''two-sided psychological entity'' (cf. Saussure, 1983: 67).

Saussure: Theory of the Sign

P Cobley, London Metropolitan University, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The sign theory of Ferdinand de Saussure (1857–1913) is principally to be found in his *Cours de linguistique générale* (*Course in General Linguistics* 1916; translated into English in 1959 and 1983). Saussure's previous work in philology and his focus on the development of Indo-European languages necessarily contains ruminations on the vicissitudes of the linguistic sign but it was his delivery of the course in general linguistics, at short notice to replace a sick colleague, at the University of Geneva from 1907 to 1911, which established his thought in this area. His posthumously published treatise of 1916 was based not on his own writings but on the notes of students present at the course. Specifically, the course was 'reconstructed' for publication by Charles Bally and Albert Sechehaye who stated in their introduction that they were aware of their responsibility to the author who "perhaps might not have authorized the publication of this text" (Saussure, 1983: xx).

The preliminary fact that needs to be taken into account, then, in relation to Saussurean sign theory is that, from the outset, it was never definitive. Readers of the *Cours* cannot be confident that Saussure's exact words are reproduced in full. Furthermore, they cannot be sure that the editorial choices of Bally and Sechehaye were not limited by what was available to them. For example, a notebook of notes in Saussure's hand, unknown to the editors, was discovered in 1996 and may force a re-reading of previous understandings of Saussurean sign theory. More important still, perhaps, is that Saussure's work has been refracted through the work of many illustrious successors beyond the realms of academic linguistics. While Saussure's *Cours* is just one, somewhat fragmented, publication that is still insufficiently read by those dabbling in sign study, the publications and teachings of his successors (or those who have invoked his name) have reached far wider audiences. The latter have had the benefit of an age of media saturation as well as a growing preoccupation with the aspects of communication that lie beyond the objects of linguistics. It is difficult to talk about Saussure's sign theory, then, without mentioning that there is also the Saussurean sign theory of Karcevskij, Vološinov, Jakobson, Benveniste, Hjelmslev, Lévi-Strauss, Lacan, Barthes, Mounin, Chomsky, Derrida, and Baudrillard, to name but a few. (Incisive discussions of a number of these are to be found in Harris, 2003).

Saussure's *Cours* projects "a science *which studies the role of signs as part of social life*" (Saussure, 1983: 15) early in the introduction, but the focus on the linguistic sign appears in Part One on General Principles. From the beginning, Saussure makes it clear that a linguistic sign is not "a link between a thing and a name, but between a concept and a sound pattern" (Saussure, 1983: 66). Moreover, "the sound pattern is not actually a sound; for a sound is something physical" (Saussure, 1983: 66). He therefore stresses that "This sound pattern may be called a 'material' element only in that it is the representation of our sensory impressions" (Saussure, 1983: 66). The linguistic sign is thus a "two-sided psychological entity" (see Figure 1).

It should be clear, then, that Saussure is not pursuing the relation between a thing in the world and the

Figure 1 The linguistic sign as a ''two-sided psychological entity'' (cf. Saussure, 1983: 67).

way that it is designated, but a psychological entity that amounts to signhood.

Proceeding to refer to the sound pattern as the *signifiant* and the concept as the *signifié*, Saussure makes clear that the former is in the mind and represents sensory impressions of sound outside the mind, while the latter consists of an abstract formulation of phenomena in the world such as 'house,' 'white,' 'see' and so forth (Saussure 1983: 65, 101ff). Saussure insisted that there was a *signifié* bound to each *signifiant* but that the reasons for their binding was not natural or pre-ordained. This fact is the first of the two fundamental characteristics of the sign: that the relation in the sign is arbitrary. He writes,

> There is no internal connexion, for example, between the idea 'sister' and the French sequence of sounds *s-ö-r* which acts as its *signifiant*. The same idea might as well be represented by any other sequence of sounds. This is demonstrated by differences between languages, and even by the existence of different languages. The signification 'ox' has as its signal *b-ö-f* on one side of the border [between French- and German-speaking regions] but *o-k-s* (Ochs) on the other side. (Saussure, 1983: 67–68; the terms *signifiant* and *signifié* are left in the original with the permission of the translator.)

To use another example, the connection between a *signifiant* 'duck' and the concept of 'duckness' was seen to be specific to the development of particular national languages. Nevertheless, Saussure did consider possible deviations from this principle, such as onomatopoeic words or signs such as those used in mime. These, somehow, seem to have a bearing which, to an extent, does suggest a preordained relationship of *signifiant* and *signifié*. But they are only deviations from the main rule. Tellingly, then, Saussure insisted that "when semiology is established . . . the main object of study in semiology will none the less be the class of systems based upon the arbitrary nature of the sign" (Saussure, 1983: 68).

The second principle upon which Saussure insisted was the linear character of the *signifiant*. This has not been the focus of semiology in the same way as the first principle has, but is nevertheless important. Saussure says that the linguistic *signifiant*, "being auditory in nature, has a temporal aspect" (Saussure, 1983: 69). What the principle of temporality entails is that the auditory sign can only exist in a linear fashion. Unlike graphic signs, it is always part of a chain unfolding. Pictures can present elements simultaneously; sounds have to wait for the connections to mount up one after another. Saussurean theories of the sign that attempted to look at nonverbal semiosis tended to elide this observation of Saussure.

Saussure insisted on four crucial factors inherent in the function of the sign:

- The arbitrary nature of the linguistic sign
- The great number of signs necessary to constitute a language
- The complex character of the system
- Collective inertia resists all linguistic innovations (Saussure, 1983: 73–74).

All of these bear upon whether the character of signs can be changed individually, a question Saussure answers in the negative. Arbitrariness seems to suggest that the sign allows free choice; however, Saussure emphasizes that words are fixed by our ancestors and that the effort required to change them is considerable and necessarily collective. This issue of freedom and its restrictions also bears upon some crucial distinctions in Saussure's *Cours* that frame his theory of the sign. For Saussure, there is an emphatic difference between *langue* and *langage*. Rendering both terms accurately in English is difficult, but *langage* refers to a linguistic faculty of humans that *requires* a *langue* among its community of speakers. *Langage*, then, comprises two things. The first is the aformentioned *langue* – the differences between all signs (with their arbitrary relations), a set so multifarious and interconnected that it amounts to a system. This collective phenomenon, potentially available to, and stemming from, all "takes the form of a totality of imprints in everybody's brain, rather like a dictionary of which each individual has a copy" (Saussure, 1983: 19). The second is *parole* – the sum total of what people say, and it comprises (a) individual combinations of words, depending on the will of the speakers, and (b) acts of phonation, which are also voluntary and necessary for the execution of the speakers' combination of words" (Saussure, 1983: 19).

Saussure emphasizes that "there is nothing collective about speech" (Saussure, 1983: 19); *langue*, however, is precisely a matter of the collectivity, the system of differences shared by all speakers. *Langue*, in fact, is the system upon which the signs in individual speech acts is predicated. Harris writes:

> The priority of *langue* as far as (Saussurean) linguistics is concerned can be boiled down to the proposition that if any episode of human speech is to be the subject of serious scientific inquiry it must be related in the first instance to a system which must be presupposed as underlying it (Harris, 2001: 121).

This is not the only way in which 'choice' over signs is subordinate to the system for Saussure.

Saussure indicates that speakers can combine linguistic signs into an infinite number 'syntagmatic'

sequences, a fact that points to a certain amount of freedom. Such sequences – syntagmas, as Saussure calls them (Saussure, 1983: 121) – are bound by relations of combination. These relations exist to facilitate the combinations **within** words and also **between groups of words**. (Within words, certain suffixes or prefixes might be subject to combinations, e.g., the suffixes *-ly* or *-less* with *name*; between words, certain combinations might be almost unavoidable, e.g., *dint* is very seldom seen without *by* preceding it and *of*' succeeding it). Yet both are also subject to associative relations (Saussure, 1983: 123–124), or associations in the mind. Thus *-less* is not just a syntagmatic relation with *name*: it is also in an associative relation with all other uses of *-less* such as *blameless*, *feckless*, *careless*. Or, an associative relation may be in operation at the level of connectedness of concepts: *teaching*, *instruction*, *apprenticeship*, etc. (Saussure, 1983: 124). This has important consequences for the role of the sign in *langue* and *parole*. Saussure introduces the sentence, phrase, or clause as an example of a syntagma, but seems to hold back from suggesting they are always the subject of individual innovations. For Saussure, it seems that some combinations are a product of both *langue* and *parole*. Post-structuralists tend to suggest that 'discourse' (meaning many things, but frequently referring to the phrase, sentence, or larger syntagma) is an arena of choice or determination beyond the realms of *langue*. This is a matter that is implicitly taken up by a number of 'Saussurean' theories of the sign. What is apparent, though, in respect of the *Cours*, is that the status of *langue* as the fundamental system of signs is drawn into question by the possibility that it may be implicated with choice in syntagma production.

The role of the 'value' of the sign is clearer. Although combination is integral to Saussure's sign theory, he insists that individual signs do not have 'meaning' or intrinsic identity. Rather, *langue* is a system of values: "A language is a system in which all the elements fit together, and in which the value of any one element depends on the simultaneous coexistence of all the others" (Sausssure, 1983: 113). This is schematized in Figure 2.

Clearly, values arise from the relationships between whole signs. Yet these relationships are based on two key points:

Values always involve:

- something dissimilar that can be exchanged for the item whose value is under consideration, and
- similar things that can be compared with the items whose value is under consideration.

These two features are necessary for the existence of any value. To determine the value of a five-franc coin, for instance, what must be known is (1) that the coin can be exchanged for a certain quantity of something different, e.g., bread, and (2) that its value can be compared with another value in the same system, e.g., that of a one-franc coin, or of a coin belonging to another system (e.g., a dollar). Similarly, a word can be substituted for something dissimilar: an idea. At the same time it can be compared to something of like nature: another word (Saussure, 1983: 113–114).

Saussure is therefore keen to emphasize the system of values rather than the intrinsic meaning of signs. Thus, famously, he notes the value of the French word *mouton*, which carries both the animal to which it refers (the sheep) and the meat that comes from it (mutton); whereas the English word *sheep* has a different value because it needs to be supplemented by an additional word, *mutton*, to refer to the animal's meat.

Saussure's conclusion on value is that "In *langue* there are only differences, and *no positive terms*" (Saussure, 1983: 118). Putting this more broadly, he argues that "In a sign, what matters more than any idea or sound associated with it is what other signs surround it" (Saussure, 1983: 118). Effectively, if one were looking for it, this is the crux of Saussure's sign theory and what imputes to it a particular character. One could argue that it is certainly the feature that seems to have drawn other 'Saussurean' sign theories to the *Cours* like a moth to a flame. Indeed, Saussure's sign theory cannot really be considered without taking into account the many extensions, bowdlerizations, revisions, and plain distortions that it has suffered. Saussure's *Cours* was rapidly taken up in many different ways, a fact that was not without its problems. Roy Harris writes:

> Within five years of its publication Saussure's *Cours* had become widely read in linguistic circles (De Mauro, 1972: 366). Translations into various languages followed. An initially critical reception gradually yielded

Figure 2 A system in which all the elements fit together (cf. Saussure, 1983: 113).

> to acceptance. By 1957 (centenary year of the eponymous Saussure's birth) it was possible for a professional academic linguist to write: 'We are all Saussureans now' (Spence, 1957). But whether they all were – and, if so, to what extent – are tricky questions (Harris, 2001: 118).

An early enthusiast for the *Cours* was the Russian, Sergej Karcevskij (1894–1955) who had attended Saussure's courses in Geneva and spread the word of their import back to Moscow in 1917. Saussurean sign theory was thus conveyed to the Moscow Linguistic Circle, featuring the young Roman Jakobson (1896–1982) and to OPOYAZ, a society that featured the Russian Formalists. One of the first major extensions of Saussure's theory of the sign, however, emanated from elsewhere in Russia. In fact, it was part of a penetrating critique by the Soviet theorist Valentin Vološinov. Vološinov (1895–1936), who had written a number of articles since 1922, published two books in the Soviet Union: in 1926, *Freudianism: a critical sketch* (1987) and, in 1929, *Marxism and the philosophy of language* (1973). Both remained virtually unknown for three decades except for the enthusiasm about the latter that was generated by Roman Jakobson in his communications to the Prague Linguistic Circle in the 1930s (Titunik, 1987: xv). At about the time that Vološinov was rediscovered in the Soviet Union, coinciding with the renaissance of Soviet semiotics (see Lucid, 1988) and leading to the translation into English of *Marxism and the philosophy of language* (1973), a number of sources began to argue that the author of Vološinov's works was none other than Mikhail Bakhtin (1895–1975) (see Todorov, 1984: 6–13).

Vološinov proceeds from an understanding of the linguistic sign as totally shot through with the social world from the outset. In fact, he devotes a considerable amount of time to criticizing "individualistic subjectivism" in the philosophy of language for simply studying words/utterances without the social dimension. His other target is the Geneva school (Saussure and his students, Bally and Sèchehaye) as representative of "abstract objectivism." Saussure's *Cours* is 'abstract' because it does not take as its main focus concrete utterances, opting, instead, for 'form' (*langue*, the non-concrete system of differences) as the basis of language study. It is 'objectivist' because it promotes the idea that this form rules concrete utterances and is the common denominator of all meaning among all people. In general, the *Cours* is argued to err in suggesting that the social world is constituted in the shared system *langue*. For Vološinov, actual utterances (*parole*) must be understood in terms of the role played by a speaker and listener: "A word is a bridge thrown between myself and another . . . A word is a territory shared by both addresser and addressee, between the speaker and his [or her] interlocutor" (Vološinov, 1973:). All signs are built to be received, even if the identity of the receiver is unclear or he or she is not present; what is important is that speaker and listener are bound in a social relationship that derives from both the utterance of signs and the wider set of social relationships in which the verbal interaction takes place. What is influential in Vološinov's *Marxism and the philosophy of language*, found also in Bakhtin, but arguably derived from dialogue with Saussure's *Cours*, is a 'dialogic' theory of the word.

Whereas Saussure sees instances of *parole* as being generated by a set of differences (in *langue*), Vološinov sees them as products of social situations. For Saussure, then, the production of utterances is ruled by purely formal laws while for Vološinov it is ruled by the multifarious nature of 'ideology.' 'Ideology' is to be understood here, as Vološinov makes clear at the beginning of *Marxism and the philosophy of language*, as both a part of reality and a reflection and refraction of a wider reality by means of signs (Vološinov, 1973: 9). Ideology is not to be understood as consciousness but as a sign system like that which makes up utterances; moreover, it fills the territory that is engendered by a verbal interaction. This, Vološinov argues, is because speakers and listeners are not concerned with the form of language, nor do they utter or hear 'words' as such; rather, they say and hear "what is true or false, good or bad, important or unimportant, pleasant or unpleasant, and so on" (Vološinov, 1973: 70). It is for this reason that any analysis of language must take into account the "*common spatial purview* of the interlocutors," "the interlocutors' *common knowledge and understanding of the situation*" and "their *common evaluation* of that situation" (see Vološinov, 1987).

In *Marxism and the philosophy of language*, Vološinov had also introduced 'theme,' 'meaning," and accent,' concepts that indicate the material fashion in which meaning is different each time an utterance occurs because the situation is different on every occasion. The term 'meaning' is quite a problematic one for both Volosinov **and** Saussure: the latter insists on 'value' rather than 'meaning' as the distinguishing attribute possessed by a sign in a system of differences; likewise, Vološinov denies the possibility that a sign can have 'meaning' on its own. But whereas Saussure locates 'value' in the interaction of signs, Volosinov finds that 'meaning' is only part of a 'theme' that resides in the whole interaction between speakers. Moreover, 'meaning' is subject to the specific socially oriented intonation of utterances that Vološinov names 'accent.' When two people are in

a room and the single word 'Well' passes between them, what does it mean? Saussure had maintained that the linguistic sign was an entity that was collective by virtue of its existence in *langue*. Yet, the collectivity that enthuses the *Cours* was not enough for Vološinov, simply because it was 'abstract' rather than concrete.

Marxism and the philosophy of language contained a major critique of Saussurean sign theory but, nevertheless, can be argued to be an extension of it. In his positing of 'theme' and 'meaning,' the latter might be said to be a concurring with the general principle of Saussure's notion of *langue*. Similarly, Vološinov does not deny that there are instances of *parole* that are generated from existing potentials. However, there would always be one factor distinguishing Vološinov's position from that of Saussure: for a sociolinguistic theory such as Vološinov's, performative rules or a system of differences are insufficient for analyzing the fortunes of the linguistic sign (Vološinov, 1987: 99).

Although Vološinov's critique of Saussure is often taken to be one of the first extensions of the latter's sign theory that has impinged upon contemporary semiotics, the closely argued essays on linguistics of Emile Benveniste (1902–1976) were taking Saussure's theory of the sign as their impetus. Benveniste was an Egyptian-born French linguist and defining figure in the thought of postwar France and beyond. Clearly, he is the father of post-structuralism, his work from the late 1930s onward paving the way for the critiques of structuralism offered by the likes of Derrida, Lacan, Kristeva, the later Barthes, Baudrillard, and assorted Anglo-American theorists in studies of film, literature, and philosophy (see Easthope, 1988). The essays in *Problèmes de linguistique générale* (1966, translated into English in 1971) ranged from a penetrating critique of Saussure's principle of arbitrariness in the sign, 'The nature of the linguistic sign,' through a series of extensions of Saussurean sign theory. These include consideration of the general role of prepositions, 'The sublogical system of prepositions in Latin,' to his essay on the third person as a non-person, 'The nature of pronouns.'

Benveniste argued in 'The nature of the linguistic sign' that the relations between the sound pattern of a sign and the mental concept attached to it were far from being arbitrary in experience. Where Saussure had insisted that the connection between a signifier and a signified was not a 'natural' one, rather it was based on convention or habit, Benveniste argued first that the arbitrary relation is one that exists between the whole sign and the object in the real world that it refers to. Relations between the *signifiant* and *signifié*, however, are not arbitrary at all for language users; in fact, the sound pattern and the concept almost seem to be as one in the human mind. In fact, the creation of a concept in the human mind that is bound with a sound pattern is rehearsed so often at an early age that it becomes an almost instantaneous process. The individual sign user cannot change the relation in English between the *signifiant* of *duck* and its *signifié*. Consequently, Benveniste's essay concludes, the connection between a sign's sound pattern and the concept with which it is bound seems almost natural and should, more accurately, be stated as a necessary rather than an arbitrary relation.

'The nature of the linguistic sign' is characteristic of Benveniste's take on linguistics: his extensions of Saussure are invariably conducted in an effort to apprehend the user's feelings in language. Benveniste's concern with the way in which signs work for the human subject points the way to further influential explorations of (post) Saussurean sign theory. In his essays on 'Subjectivity in language' and 'The nature of pronouns' collected in *Problèmes de linguistique générale*, Benveniste sought to demonstrate how signs under certain linguistic categories not only allow human subjects to refer to themselves but actually create the parameters of human self-consciousness. He writes,

> 'Ego' is he who *says* 'ego'. That is where we see the foundation of 'subjectivity' which is determined by the linguistic status of 'person'.
>
> Consciousness of self is only possible if it is experienced by contrast. I use *I* only when I am speaking to someone who will be a *you* in my address (Benveniste, 1971: 225).

Because *I* is a linguistic sign – and therefore usable by the whole linguistic community – it cannot begin to represent the fullness of one human being's self-consciousness. It is only a word. However, as relations in the linguistic sign are necessary, it invariably feels natural to humans that the word does have this power to represent.

In this light, it is easy to see how Benveniste so influenced post-structuralism. "It is in and through language that man constitutes himself as *subject*," he writes, "because language alone establishes the concept of 'ego' in reality, in *its* reality which is that of being" (Benveniste, 1971: 224). For Benveniste, the separation of *I* and *you* in dialogue was crucial to the category of *person* because it is the means by which the individual sets himself or herself up as a subject in discourse. The personal pronouns are just one, albeit most important, means by which each speaker appropriates a language; deixis is another means, demanding that meaning can only be realized with reference

to the instance of discourse in which the deictic category appears. As such, language creates the designation of person; but it also contributes to the human understanding of such supposedly autonomous phenomena as time and space.

Benveniste recognizes in Saussure's theory of the sign a fundamental split that he extends to the realm of subjectivity. If the relations in the linguistic sign are 'arbitrary' when placed under analysis, but 'necessary' (felt to be natural and automatic) when used, it is possible that this indicates the subject of signs is pulled two ways. Benveniste identifies two sides of any use of language: he calls these *énoncé* and *énonciation*. The *énoncé* is simple enough: it is the statement or content of the particular instance of language, what is being said. The *énonciation*, on the other hand, is the act of utterance and presupposes a speaker and a listener. The two can be recognized when separated in this abstract way but, in practice, they are always entangled. The subject of this dynamic in linguistic signs is in a dilemma. There will be the rendering of himself or herself as a subject represented in the use of pronouns such as *I* (*énoncé*); but there will also be that other 'I' who does the rendering (*énonciation*). The dilemma, here, is made clear in such paradoxical constructions as *I am lying*, in which the subject speaking **must** be separate from the subject represented in the instance of discourse.

If Benveniste's furthering of Saussurean sign theory took place in relation to a theory of the subject, Louis Hjelmslev's contemporaneous co-opting of Saussure was more oriented to the extension of the system. A Danish linguist and member of the Copenhagen School of linguistics, Hjelmslev founded the post-Saussurean linguistics called glossematics. Effectively, glossematics extended Saussure's investigations into *la langue*, particularly the latter's insistence that this is a form and not a substance. Harris writes,

> Glossematicians took the Saussurean dictum that *langue* is "form not substance" (Saussure, 1916: 163) to its logical conclusion, and argued that the languages now in existence and available to observation are merely historical realizations of certain systems that could equally well exist in other manifestations (not necessarily spoken and not necessarily written either). Thus "the task of the linguistic theoretician is not merely that of describing the actually present expression system, but of calculating what expression systems in general are possible as expression for a given content system, and vice versa" (Hjelmslev, 1970: 105) (Harris, 2001:128).

Whereas Hjelmslev had previously focused on distinctive features as elements of form in his early work, glossematics sought to identify systematic 'functioning' of signs. He embarked on an identification of signs in *langue* as, precisely, 'functions' in relation to 'functives.' A function exists, for example, between a class and its components, a chain and its parts or a paradigm and its members (or between members or parts or components). A functive, on the other hand, is the 'terminal' – at either end – of a function.

Hjelmslev proceeds from the preliminary notions that language is a system of signs and that the sign – by virtue of its being for someone – must be construed as a function. However, he insists that the sign conceived in this way must be clarified as a 'sign-expression.' As such, then, there are two planes to be considered in the analysis of language as a sign system. The first is the 'expression plane,' which has both a form and a substance. The second is the 'content plane,' which has the same. Both are made up of a restricted number of non-sign entities, *figurae* (such as phonemes), which can combine to produce an unlimited number of signs. The fact that there are two planes of the sign means that, for Hjelmslev, the notion of the sign as simply for someone is limited. This view tends to see the sign as a matter of an indication by an 'expression' of some external 'content,' whereas the Saussurean view, according to Hjelmslev, sees the sign as generated by the connection between an expression and content. If the sign relation is seen as a function, however, the functives of expression and content can never be separable and this has consequences for the conception of the sign. Chiefly, Hjelmslev's work contends that the sign does not just indicate; rather it is made up of 'content substance' ordered into 'content form,' is juxtaposed for sign users with other examples of content form (e.g., *ring* might indicate both jewellery for the finger and something that emanates from the telephone), and is constituted also on the plane of expression as an 'expression form' (containing specifically organized *figurae*), which is itself ordered to an 'expression substance' (other pronunciations, other enunciations by other people, etc.).

Hjelmslev's glossematics thus instituted a procedure that treated all text elements as relations of function within expression and content. Yet, because the relation of function was seen by him as all important, and because both were made of ('meaningless') *figurae*, those elements that make up 'expression' and those that make up 'content' are to be considered interchangeable. It was the combination of Hjelmslev's resolute systematization and his facilitation of the mutability of planes according to function that made his glossematics so amenable to other structuralist linguists and thinkers.

The early work of Roland Barthes (1915–1980) marks him, perhaps, as heir to Hjelmslev as much as to Saussure. This is clear in some of Barthes formulations such as 'denotation,' 'connotation,'

and 'metalanguage.' However, ultimately, Barthes saw himself as furthering Saussure's sign theory and, certainly, initiating Saussure's vaunted project of a semiology, a science that studies the life of signs within society. Commentators tend to agree that Barthes's work developed significantly enough during his career for there to be a manifest difference between the early and later Barthes. Usually, it is assumed that the earlier Barthes is a semiologist concerned with Saussure's sign theory, while the later breaks with this. However, it is not too difficult to see extensions and continuities of Saussure from *Mythologies* (1957) to *S/Z* (1970). Barthes book of 1964, *Elements of semiology* (translated into English, 1967a), is particularly noteworthy because it purports to be both a treatise and a primer of Saussurean theory of the sign. Indeed, *Elements of semiology* has been, in many instances, almost taken as the word of Saussure rather than Barthes.

For Barthes in *Elements of semiology*, it is the repetition of signs in successive discourses that entails that each sign become an element of the language (*la langue*, "language without speech" [Barthes, 1967a: 14–15]). However, according to Saussure, *langue* is a heuristic means for thinking about the language system; language without speech would actually be impossible. Barthes was keen to explicate an understanding of language not as a collection of discrete signs but as an organizing principle of discursive fields. Such discursive fields would not be constituted by verbal signs (and their connections) alone. Barthes therefore draws attention to the fashion system, where signs work in a somewhat different way. For Barthes, the garment cannot be an instance of speech; rather, it is always "a systematized set of signs and rules: it is a language in a pure state" (Barthes, 1967a: 26). This is because "fashion clothes (as written about) are the language at the level of vestimentary communication and speech at the level of verbal communication" (Barthes, 1967a: 26). The feature of the sign that seems to be most crucial for Barthes and that encourages him to make the counterpoint to Saussure is the idea of the sign as part of an 'ideological' organizing principle. Whereas individual or collective uses of speech (or individual or collective usages of food, the analogous example he uses; Barthes, 1967a: 28) might become part of language (or alimentary language) as a result of repetition or evolution, what makes up the constituents of 'language' in the case of fashion is the highly directed work of a 'deciding group.'

Elements of semiology makes it apparent that central to his theory of the sign is the way that it can be not simply an ideological vehicle but, in fact, ideological through and through. This is apparent in his comments on the nature of the *signifiant* and the *signifié* (usually translated into English, potentially confusingly, as 'signifier' and 'signified'). Nevertheless, Barthes's formulations in this area are the subject of some questions regarding their consistency and their Saussurean credentials. One reason for this is suggested by Roy Harris: that Barthes came to Saussure relatively late and that his understanding of the Saussurean sign was already refracted through the lens of his reading of Lévi-Strauss, Lacan, Jakobson, Martinet, Benveniste and, as noted above, Hjelmslev (Harris, 2003: 136). In respect of the latter, Barthes introduces accurate definitions of the *signifiant* and *signifié*, for example, but immediately reframes their operation in terms of form, substance, plane of expression, and plane of content (cf. Hjelmslev, 1970).

Barthes is initially very clear about the *signifiant* and *signifié*: they are an acoustic image and a mental concept, respectively. He underlines the latter, in fact, by writing "the signified [*signifié*] is not a thing but a mental representation of the thing" (Barthes, 1967a: 42). However, Harris points out that while Barthes's formulations about the internal relations in the sign are unexceptional, his definition of what the sign (*signe*) is, concentrating on the relation between *signifiant* and *signifié*, misses its mark. For Harris, Barthes

> fails to see that for Saussure the *signe* is indeed not only a linguistic unit but *the* linguistic unit, and not a mere 'rapport' between its constituent parts. *A fortiori*, the fundamental Saussurean tenet that in *la langue* semiological relations take priority over – and determine – units sinks without trace in Barthes' exposition ... Barthes had not only missed the most original theoretical feature of Saussure's account of linguistic structure, but reinstated precisely the concept that Saussure was at pains to reject, i.e., the sign as a mere correlation between antecedently given items (formal and semantic) (Harris, 2003: 141).

Yet Barthes' placing of the sign before the semiological relations of *la langue* has a further twist that has been undoubtedly influential and has served to distort the picture for those who take the account in *Elements of semiology* to be the definitive exposition of Saussure. In drawing attention to the "nature of the signifier [*signifiant*]," Barthes writes that

> it is purely a *relatum*, whose definition cannot be separated from that of the signified [*signifié*]. The only difference is that the signifier is a mediator: some matter is necessary to it. But on the one hand it is not sufficient to it, and on the other, in semiology, the signifier can, too, be relayed by a certain matter: that of the word. This materiality of the signifier makes it once more necessary to distinguish clearly 'matter' from 'substance': a substance can be immaterial (in the case of the substance of

> the content); therefore, all one can say is that the substance of the signifier is always material (sounds, objects, images) (Barthes, 1967a: 47).

It is fairly clear why Barthes makes this un-Saussurean assertion about the *signifiant* and, indeed, he is not shy about it:

> In semiology, where we shall have to deal with mixed systems in which different kinds of matter are involved (sound and image, object and writing, etc.), it may be appropriate to collect together all the signs, *inasmuch as they are borne by one and the same matter*, under the concept of the *typical sign*: the verbal sign, the graphic sign, the iconic sign, the gestural sign are all typical signs (1967a: 47).

For Barthes, the business of establishing a semiology in which verbal and nonverbal signs can be considered equally leads him to override Saussure's fundamental principle in which the relations within the linguistic sign are purely mental. This is probably the most characteristic feature of Barthes's theory of the sign, although, unfortunately, the fact that *Elements of semiology* has often been treated as a faithful explication of Saussure rather than as a manifesto, has prompted the erroneous belief that Saussure's *signifiant* is the same as Barthes' (see, for example, Bignell, 1997; Cobley, 1996).

Another feature of Barthes' revision of Saussure concerns the vaunted 'arbitrariness' of relations in the sign and, here, Barthes takes his cue from Benveniste and then Martinet. In respect of the word *ox*, Barthes suggests, after Benveniste, that the relation of *signifiant* and *signifié* "is by no means arbitrary (for no French person is free to modify it), indeed, it is, on the contrary, necessary" (Barthes, 1967a: 50). Ultimately, however, Barthes suggests that the relation is one that is determined by different degrees of 'motivation.' An unmotivated system, he argues, is one where signs are not founded by convention but by unilateral decision; so, for him, signs in *la langue* are not unmotivated but signs in the world of fashion (where there is an elite organizing body) are. Signs are motivated, on the other hand, when the relation between *signifiant* and *signifié* is analogical (Barthes, 1967a: 51). This is evidence of Barthes' attempt to smooth the transition from Saussure's linguistic sign to a general semiology containing, for example, pictorial signs whose *signifiant*/*signifié* relation is, frequently and unavoidably, one of motivation.

It is evidently important for Barthes that there be an analytic unity in his theory of both verbal and nonverbal signs, chiefly because the ravages of ideology, when exposed, would be less convincing if they were distributed unevenly across different kinds of signifying system. Indeed, Barthes' justly famous essays on photography (1977a, 1977b) are important in this respect since they indicate that the denotative sign enacts a motivated relationship often as if it were in the service of 'validating' the injustice of the connotative sign, establishing its literalness and helping to ground ideology. Barthes's close analytic readings, many of them informed by an implicit use of Saussure's notion of syntagmatic–paradigmatic interaction, have informed the practice of students of media, culture, and communications to the present day, although the later work of Barthes is often assumed to transcend Saussurean sign theory as though his earlier work did not. In a later book, *S/Z* (Barthes, 1970), Barthes does consider signs from a slightly different angle. However, one could argue that this work still struggles with the vicissitudes of the Saussurean sign.

In the opening pages of *S/Z*, Barthes formulate two kinds of texts, the 'readerly' and the 'writerly,' where the reader is respectively an idle consumer of the signs in the text or a diligent producer of it, almost rewriting what is presented (Barthes, 1974: 3–4). Barthes goes so far as to actively advocate the latter position but, curiously, the intense analysis that follows these comments and makes up the majority of the book produces an implicitly conflicting conclusion. *S/Z* dissects a Balzac short story, 'Sarrasine,' dividing it up into very brief segments and by elaborating five codes through whose matrix the text passes. The result is to expose an abundance of meanings, making a text that might have been billed as a 'simple realist narrative' into one that now threatens to be eminently 'writerly.' It is not clear whether Barthes set out to demonstrate that 'realist' texts – exemplified by 'Sarrasine' – somehow carried signs that purported to possess a 'stable,' one-to-one *signifiant*/*signifié* relationship. Yet, if this was Barthes's intention, then it is clear that the final delivery of *S/Z* stymied it. The Saussurean version of the sign was by no means complicit with 'readerly' texts; indeed, the analysis might suggest that post-Structuralist versions of the sign were not guaranteed to produce 'writerly' texts.

If one feature of Barthes's analyses has been an extension of Saussurean sign theory to make it almost synonymous with the analysis of everyday phenomena (as opposed to an element in the understanding of linguistic systems), then his work is of a piece with that of the enormously influential structuralist anthropologist, Claude Lévi-Strauss (b. 1908). To be sure, Lévi-Strauss was heavily influenced by a number of thinkers (Marx, Kant, Durkheim, Mauss, Jakobson) but most prominent among these, perhaps, was Saussure. Lévi-Strauss's work until the mid-20th century focused on kinship systems and marriage rules, while later he concentrated on belief systems

embodied in myths and religion. Inspired by phonology, Lévi-Strauss had developed a methodology to investigate marriage alliances and myth. Yet, more specifically, crucial to Lévi-Strauss's conception of anthropology was Saussure's insistence on how the differentiality between linguistic signs gives rise to value (*valeur*).

Rather than carrying intrinsic 'meaning,' Saussure argued that linguistic terms were imbued with an identity that relied totally on their difference to other terms. For Lévi-Strauss, in turn, differentiality characterized a range of anthropological phenomena, particularly in the practices of exchange to be found in kinship rules, but also elsewhere. This included such binary formulations as the 'raw' and the 'cooked,' one of a number of anthropological oppositions discussed at length by Lévi-Strauss in a Saussurean spirit heavily refracted through the work of Jakobson and Troubetzkoy. Taking the oppositions instanced by phonemes as the smallest possible units participating in the differentiality of language, Lévi-Strauss proceeded to formulate both a study of myth and of 'savage' thought in general. The analogy of phonemes combining and opposing to produce linguistic signs that might be employed in systems of exchange informed, for example, his analysis of kinship.

In his theory of myth, Lévi-Strauss considered mythic narratives to rely on 'mythemes' – a term that directly echoes 'phonemes,' of course. The conclusions that Lévi-Strauss reached about Saussure – that "language can be analyzed into things which are at the same time similar yet different" (Lévi-Strauss, 1977: 209) – encouraged him to concentrate on the 'form' by which phonemes were combined rather than the strictly semantic orientations of a myth's content. Lévi-Strauss thus devised a method that enabled him to break down all myths to allow the identification of a basic substrate. The most famous example of this is his 1955 interpretation of the Oedipus myth in which he treats it "as an orchestra score would be if it were unwittingly considered as a unilinear series" (Lévi-Strauss, 1977: 213).

Say, for instance, we were confronted with a sequence of the type: 1, 2, 4, 7, 8, 1, 3, 4, 6, 8, 1, 4, 5, 7, 8, 1, 2, 5, 7, 3, 4, 5, 6, 8 . . . the assignment being put to all the 1s together, all the 2s, the 3s, the result is a chart:

1	2		4			7	8
	2	3	4		6		8
1			4	5		7	8
1	2			5		7	
		3	4	5	6		8

(Lévi-Strauss, 1977: 213)

He then goes on to break down the features of the Oedipus myth – for example, 'Oedipus marries his mother, Jocasta' and 'Antigone buries her brother, Polynices, despite prohibition' (Lévi-Strauss, 1977: 214) – which he reorders in a similar way. Effectively, Lévi-Strauss comes up with four columns of relations in the myth: (a) overrating of blood relations; (b) underrating of blood relations; (c) slaying of monsters; (d) (names for difficulty of balance/standing). These mythemes suggest that the orchestrated myth has at its core a common human concern: anxiety over our origins. Put another way, the myth plays out the drama of humankind's quest to determine whether it has been forged in blood/earth or by human reproduction.

In the face of post-structuralism's revisions of his theoretical position and, in particular, the critique leveled by Jacques Derrida, Lévi-Strauss remained an unrepentant reductionist, revealing in his work the *langue* behind copious examples of *parole*. Lévi-Strauss was not alone in proposing such broad formulae at this time. In a series of articles in the late 1950s and early 1960s, which culminated in the 1966 book, *Sémantique structurale*, A. J. Greimas (1917–1992) worked out a semiotic project influenced by Hjelmslev and Saussure. Considering myth and narrative, Greimas, in a fashion that, from a distance at least, seems akin to that of Lévi-Strauss, gave priority to structural relations between narrative entities rather than to their intrinsic qualities. Lévi-Strauss, along with Vladimir Propp (1895–1970) and Greimas, effectively gave birth to the discipline known as 'narratology.' Narratology is a specific way of understanding narrative that was developed out of Russian Formalism but relied to a large extent on the theory of the sign put forth by Saussure. Sometimes 'narratology' is the name given to any form of analysis of narrative, but this is misleading. The term, instead, refers to a particular period in the history of narrative analysis that has had important consequences for other areas of study but that has also, itself, been transformed by other disciplines and perspectives. What characterizes narratology most readily is a systematic, thorough, and disinterested approach to the mechanics of narrative – an approach that provides a stark contrast to those that observe or seek out 'value' in some narratives (and not others) or that provide hierarchies of narratives based on spurious categories such as the 'genius' of an author or artiste.

Roland Barthes's essay 'Introduction to the structural analysis of narratives' (Barthes, 1977, [1966]) and Tzvetan Todorov's *Grammaire du Décaméron* (1969), the latter of which actually coined the term '*narratologie*,' represented the birth of narratology

proper. In the late 1960s and early 1970s, these paved the way for works by names frequently associated with the narratological enterprise: Mieke Bal, Seymour Chatman, Dorrit Cohn, Gérard Genette, and Gerald Prince. The fundamental distinctions in narratology between, for example, 'plot,' 'story,' and 'narrative,' were, in different ways, developed by the immediate precursors of the main narratological enterprise who came after Russian Formalism. Both Propp and Lévi-Strauss undertake analyses of narrative that focus on 'story' or, in the latter's case, in an extension of the linguistic terminology from Saussure, 'semantic structure.' In *Morphology of the folktale* (originally published in Russian in 1928, then auspiciously translated into English in 1958, appearing in book form 10 years later), Propp analyzed 100 Russian folk stories. Rather than attending to the surface differences of the narratives, he examined their underlying commonalities, particularly the basic function of actions in each story. Propp identified 31 functions characterizing the tales: for example, 'One of the members of a family absents himself from home'; 'An interdiction is addressed to the hero'; 'The interdiction is violated'; through to 'The villain is punished' and 'The hero marries and ascends the throne.' Each of these functions is, of course, carried out by one or more of the *dramatis personae*. Propp therefore proceeded to isolate the seven basic roles of characters in his sample, listing the particular sphere of action to which each belonged: the hero, the villain, the princess (sought-for) and her father, the dispatcher, the donor, the helper, and the false hero.

As differential signs in narrative, which Propp named 'functions,' it was easy to see the connection between such elements and Saussurean sign theory as adjusted by Hjelmslev. It is in this frame that the categories introduced by Greimas were so influential. Most importantly, Greimas emphasizes the functional nature of Propp's *dramatis personae* by referring, instead, to 'actants.' 'Actants' or 'actantial roles' are defined in the following ways: in relation to each other, in relation to their place in the narrative's 'spheres of action' or 'functions,' and in relation to their place in the logic of a narrative. In Greimas's revision of the *dramatis personae* in *Structural semantics* (1983, [1966]), the actants comprise 'subject vs. object,' 'sender vs. receiver' and 'helper vs. opponent,' a set of categories that replaces Propp's analysis based on character roles (heroes vs. sought-for person, father/dispatcher vs. hero, helper/provider vs. villain/false hero). Narrative meaning in this formulation is played out through the various functions: thus, the 'subject' searches for the 'object'; the 'sender' is on a quest, initiated by a 'subject' for an 'object'; and so on. In addition, Greimas explores the way in which the structure of narrative can be defined by the interaction of 'positive' and 'negative' functions such as the opposition between a relationship designated *A* and containing 'command/behest' (*a*) and 'acceptance' (*non a*), and a relationship designated *A* • consisting of 'violation' (*non a* •) and 'interdiction' (a •). Ultimately, the systematic scrutiny of these relations led Greimas to posit a 'semiotic square' of such coordinates as a tool for the analysis of narrative meaning.

The work of Greimas, as well that of many others, such as Barthes, had traveled a long way since adopting broadly Saussurean principles. Indeed, the extensions of Saussurean sign theory were often actually extrapolations from Saussure as explicated in the work of other linguists or cultural theorists. Another case in point is the sign theory of Jacques Lacan (1901–1981), which is heavily reliant on the work of Jakobson, Lévi-Strauss, and, especially, Benveniste. For Lacan as a psychoanalyst, the chief point about the linguistic sign was that it somehow misses something; it is unable to express the purely personal. This is because relations in the sign are arbitrary, allowing the same sign to be used by everybody else. In 1957, Lacan delivered a lecture at the Sorbonne entitled 'L'instance de la lettre dans l'inconscient ou la raison depuis Freud,' which incorporates a significant extension of Saussure's sign theory, while also pursuing a series of related questions evident in Lacan's work since the completion of his Ph.D. dissertation in 1932 (see Benvenuto and Kennedy, 1986: 107; Payne, 1993: 74).

Taking the fundamental constituent of the *Course in general linguistics*, Saussure's map of the sign with *signifié* on top of *signifiant* enclosed by an ellipse, Lacan inverts it and opens it up. He presents a picture of two identical doors distinguished only by the writing that appears above them (**Figure 3**).

Figure 3 Lacan's twin doors. From Lacan, 1977.

Clearly, this is a version of Saussure's map (or algorithm) of the sign (**Figure 4**).

What is important here is that the priorities of Saussure are reversed by Lacan. The *signifié* (or mental concept) of what lies behind each door is determined entirely by the *signifiant* (what should be the 'sound pattern,' here, is translated without comment by Lacan into a written notation: 'Ladies,' 'Gentlemen') that lies above the door. A whole cultural law – as Lacan puts it, the subjection of public life to the law of urinary segregation – is engendered by the existence and location of the two *signifiants* as well as their difference from one another. Lacan seeks to demonstrate that the mental concept is created by the way in which language operates. So, in addition to inverting the priorities in the algorithm, Lacan also banishes the ellipse and reinforces the bar that separates *signifiant* and *signifié* to emphasize that there is an incessant possibility of the *signifié* sliding under the *signifiant*. The *signifiant* is therefore responsible for the birth of subjectivity; however, it does not give birth to the human as a whole. There remains in the human a complex domain of desires – the unconscious – ruled by an order that is totally different from that of the social institution, language.

The implications of Lacan's inversion of the Saussurean algorithm for the study of subjectivity are fairly clear. As such, his work was taken up in all manner of areas in the humanities. It was especially influential in film theory circles, particularly in the 1970s in Britain. Problematically, however, it was frequently seen as correcting the fundamentals of Saussure's sign theory (or, as was frequently the case, misrepresenting his theory of the sign in order to carry out some fixing that was never needed in the first place) or, worse, seen as standing for the truth of the Saussurean sign. This is a pattern that can be seen in other Saussurean sign theory, especially in the Gallic tradition – for example, Derrida (1976: 27–73) and Baudrillard (1983) – but also as Saussurean sign theory was used as a central figure in other disciplines (see, for example, Coward and Ellis, 1977; Culler, 1975; Hall *et al.*, 1980; Dyer, 1982; Fiske, 1990; Bignell, 1997; Hall, 1997; Cobley, 1996). Yet there is one area of Saussurean sign theory which has been of utmost importance to its dissemination and must be briefly mentioned here.

Figure 4 Saussure's sign. From Saussure, 1983: 113.

In his indispensable volume on *Saussure and his interpreters* (2003), Roy Harris discusses the Students' Saussure, the Editors' Saussure, Bloomfield's Saussure, Hjelmslev's Saussure, Jakobson's Saussure, Lévi-Strauss's Saussure, Barthes's Saussure, Chomsky's Saussure, Derrida's Saussure, and History's Saussure. Implicitly discussed, but it could also have merited a chapter of its own, would be the translators' Saussure. The English translation of the *Cours* is interesting in itself and, indeed, as Harris himself produced the second translation of the *Cours* in 1983, modesty may have prevented him from discussing the issue in his volume. However, it should be noted that the first English translation of 1959 has damaged the understanding of the *Cours* and caused it to be falsely applied in various areas. One example from Wade Baskin's translation of 1959 will suffice to illustrate the problem. It is the rendering of *signifiant*, *signifié*, and *signe* as 'signifier', 'signified,' and 'sign.' The first of these items produced the major misunderstanding. In short, it gave the impression to English natives that the *signifiant* was anything that did the work of signifying or, to put it another way, a sign. This was precisely the formulation that Saussure wanted to avoid and Saussure is explicit about this on a number of occasions in the *Cours*. The term for the *signifié*, at the same time, seemed to imply anything that was the object of signification – that is to say, any **thing** that was being **signified**, whether that be a thing in the head or a thing in the world (with the implication that it was generally the latter). At a stroke, Saussure's psychological conception of the sign was lost and versions of semiology were given free rein to look at the whole panoply of cultural artifacts as if they embodied a *signifié/signifiant* relationship. In his 1983 translation, Harris did his best to regain some of the ground that had been lost by rendering *signifiant* and *signifié* as 'signal' and 'signification' in an attempt to give a more accurate flavor of Saussure's sign theory and to head off erroneous extrapolations. However, the damage was already done and Harris' terms have not been widely taken up as yet. (Thus the present article retains the original French terms).

What is beyond doubt is that Saussure's theory of the sign has been extraordinarily influential and has generated some productive work while also spawning some monsters. The posthumous provenance of the *Cours* has, perhaps, entailed that the 'real Saussurean sign theory' will never be known. However, two points should be added. The theory of the sign in Saussure's *Cours* is still unfolding as new discoveries about the original Geneva course in general linguistics are made (see Harris, 2003: 214–252). And, while it may not be the word of

Saussure himself, Saussure's *Cours* is still insufficiently read.

Saussurean Tradition in 20th-Century Linguistics

C Sanders, University of Surrey, Guildford, UK

© 2006 Elsevier Ltd. All rights reserved.

Ferdinand de Saussure is considered one of the founding fathers of the modern science of linguistics (*see* **Linguistics as a Science**) and the main source of European structuralism (*see* **Structuralism**). He has come to stand as something of a figurehead, often cited in writings on the history of linguistics as the starting point, or key turning point, for the discipline as we know it today. For several years his name served as a shorthand reference for all that is good – or bad – in the structuralist approach. The fact that he did not himself publish the main volume that gave access to his thought, along with the widespread uses and abuses that were made of his theory (mainly in disciplines outside linguistics), attributed to him a mythical status that has sometimes obscured the true nature of his contribution to linguistics. However, with hindsight many of the debates surrounding the interpretation of his *Course in general linguistics* (the *Cours de linguistique générale* [*CLG*] was first published in French in 1916) can be seen as determined by changing intellectual fashions. With the current publication of new manuscript materials, a more balanced assessment of his contribution to linguistics may be reached.

Saussure is arguably the late-19th-century linguist who was most conscious of the stakes involved in the creation of a new discipline or paradigm. The papers collected in his *Writings in general linguistics* (originally published as *Ecrits de linguistique générale* [*ELG*] in 2002) demonstrate a strong awareness of epistemological issues and include a wealth of examples of his attempts to forge a terminology that would be capable of expressing the key concepts of the new approach. He constantly articulated his desire to develop a rigorous conceptual and methodological basis for descriptive linguistics and to define the boundaries of linguistics and its relation to neighboring disciplines, predicting its close affinities with, but separateness from, sociology and – especially – psychology. He is responsible for the term '*sémiologie*' to describe the future science of signs (*see* **Semiotics: History**), of which language would be just a part (albeit the major part), and he showed great vision in his clear but sometimes implicit references to language typology and embryonic generative rules. While the heated debates around certain Saussurean terms and concepts in themselves constituted an indirect tribute to his ideas, for many years there were only a few exceptional acknowledgments by linguists of his epistemological and terminological contribution to linguistics, with explicit recognition being for a time left largely to nonlinguists. Yet his concepts and terms are ones that linguistics cannot do without, and that have permeated most strands of 20th-century linguistics (*see* **20th Century Linguistics: Overview of Trends**) in one way or another. Indeed, our first measure of Saussure's importance is the pervasive and central role that the concepts and terms developed by him continue to play in both linguistics and in a range of disciplines. The terms of the *CLG*, such as 'synchronic,' 'paradigmatic,' '*langue*,' '*parole*,' '*signifiant*,' and '*signifié*' are now part of the metalanguage of the discipline, and the difficulty of translating the last four terms adequately and their acceptance as loanwords in a number of languages testifies to Saussure's achievement in rigorously honing key concepts that interlock to make a complete and coherent theory of the way in which communication is made possible.

The *CLG* is a posthumous compilation from some of the notes taken by students at Saussure's lecture series given at the University of Geneva from 1907 to 1911 and edited by Bally and Sechehaye. It has run into numerous editions, with the page numbering remaining the same from the second edition on, included in the excellent scholarly edition annotated by De Mauro. The main reading of the *CLG* in the second half of the 20th century was a structuralist one, which at first stimulated much comment and further scholarship both in linguistics and in other disciplines. In linguistics it influenced scholars from Hjelmslev in Denmark to Coseriu in Germany, and it contributed to the theoretical underpinning of descriptions of contemporary French and structuralist semantics. However, as the fashion for structuralism waned, Saussure came to be seen – misleadingly, it now seems – as offering a reductionist view of language as a code, and, particularly by Marxist critics, as denying the historical dimension of language. Saussure's insistence on the language system was held to exclude considerations of both language variation and of the speaker, which allowed some to lay at his door the tardy development of sociolinguistics in parts of Europe. New material emerged, especially pertaining to Saussure's study of anagrams in classical poetry. In addition, the comparative edition of lecture notes drawn up by Engler threw light on some of the choices made by the editors of the *Cours*, all of which led to a revised interpretation of his work. It began to be understood that for a philosopher such as Merleau-Ponty, who emphasized the potential of a theory that showed

meaning to emerge from the space between units, Saussure was anything but reductive. Similarly, Saussurean theory was not necessarily incompatible with pragmatics or theories of *énonciation*. Furthermore, with the publication of notes written for a philosophical book on language ('On the dual essence of language,' in *ELG*) and the preparatory notes for his Geneva lecture series, it has now become to some degree possible to trace the evolution of Saussure's thought in a way that does not lead us to reject the *CLG* but to arrive at a more flexible interpretation of it.

It should not be forgotten that Saussure's early reputation was made by his brilliant work in the field of historical and comparative grammar (*see* **Historical and Comparative Linguistics in the 19th Century**) (for the continued importance of his work on the Indo-European vowel system, see Morpurgo Davies, 2004). Nevertheless, he is famous for helping to establish the synchronic study of language, and in the *CLG,* the first methodological distinction in Saussure's tightly knit theory is the necessary separation of synchronic (descriptive) from diachronic (historical) linguistics (*see* **Synchronic and Diachronic Variation**). Saussure was not alone: at about the time of his Geneva lectures, for example, American linguists such as Bloomfield and Sapir were committed to a descriptivist approach. However, it is difficult to appreciate how deeply entrenched the historical approach was in Europe as a result of the hegemony of 19th-century German scholarship, so that linguists who wished to promote the study of the contemporary language, such as Saussure's Paris colleague Bréal, nonetheless continued to confuse the synchronic and diachronic approaches. It was Saussure who understood that our whole understanding of language as a system depended on the rigorous observation of this distinction, as therefore did the very foundations of the discipline of linguistics. The categorical and sometimes schematic expression of this observation in the *CLG* led some linguists, such as Roman Jakobson and those in the Russian tradition, to accuse Saussure of a 'static' conception that ignored the constant flux of language (see Hutchings, 2004). If it was not clear to the reader of the *CLG* that this was not Saussure's intention, it certainly became clear in the *ELG,* where Saussure said that "language is, at every moment of its existence, a historical product"(translation of *ELG*: 209*)*.

The next well known methodological distinction is the tripartite one between *langage/langue/parole*, which is often reduced to a *langue-parole* dichotomy. The reader of *ELG* is party to the linguist's working his way toward a definition of these concepts; by the third 'cours' on which the *CGL* is largely based, the concepts were more or less established, although the terminology fluctuated occasionally. '*Langage*' is the overarching term for the human phenomenon of language; '*langue*' refers to both the underlying linguistic structure and to the speaker's mental representation of it; and '*parole*' refers to language in use. It was Saussure's contention that priority had to be given to a '*linguistique de la langue,*' but that a '*linguistique de la parole*' would follow. The fact that he did not live long enough to complete the latter has, of course, led to the criticism that he neglected real language use, discourse, and the subjectivity of language.

In a rare example of Saussure's remaining hidebound by the legacy of 19th-century linguistics, he regarded syntagmatic relations that went beyond the word or fixed phrase as 'belonging' to *parole*. He gave what is probably the most coherent account of the essentially differential and relational nature of basic linguistic units and the way in which the functioning of these makes linguistics a science of values. However, whereas the latter can be of relevance at all levels of linguistic analysis, he illustrated it mainly with examples from phonology and morphology. While he could envisage structuralist semantics and semiology (although he himself used the word 'system,' not structure, with reference to language), he accorded almost no attention to syntax in the *CLG* and very little more in the *ELG*. This glaring *lacune* apart, he nevertheless stated his conviction that communication and discourse constituted the essential context of linguistic analysis ('Language is created only with a view to discourse'/'La langue n'est créée qu'en vue du discours,' *ELG*: 277). Each linguistic unit – each phoneme and each word – is a sign, characterized by Saussure as being linear and arbitrary. In the mid-20th century in some circles, the arbitrary nature of the sign made nearly as much ink flow as the debate about *langue/parole*, largely because the distinction between 'arbitrary' and 'unmotivated' was poorly understood; for Saussure, linguistic units could be more or less motivated within the system (e.g., derivatives from one part of speech to another), but the whole system was inherently arbitrary. More crucially, the linguistic sign for Saussure linked the mental representation ('*signifiant*') of the utterance with the mental representation of the referent ('*signifié*'). This proposal that only the signifier and the signified should be considered as part of linguistics proper is one of the most lucidly expressed and innovatory of Saussure's ideas, but, despite the widespread use of these terms, there is still a tendency to confuse 'signified' and 'referent.'

The initial reception of Saussure's work in the English-speaking world was relatively muted.

Contemporaneous with Saussure's attempt to define the functioning of meaningful units of sound was the work of British phoneticians Sweet, Ellis, and A. G. Bell, to whom Saussure refers in the *ELG*. Although the British school saw phonetics as the starting point for the new descriptive linguistics, for Saussure '*phonologie*' (which in the fluctuating usage of the time was his term for what we now call 'phonetics') was not part of the core study of the language system. Ogden and Richards, among the first to comment on the *CLG*, took issue with Saussure's dyadic account of the sign, which, in contradistinction to their own triadic model, excluded the referent. The warmest early praise for the *CLG* in Britain probably came from Gardiner (*The theory of speech and language,* 1932), who himself had proceeded to write the 'linguistics of *parole*' that had been left undone by Saussure. The perceived lack of emphasis on language in use and on language variation seemed to make Saussure something of an irrelevance to British linguists for whom both were major concerns. Although Firth famously claimed that "we are all Saussureans now," it could be argued that his own work and that of the so-called London School shows little Saussurean influence. Once American structuralist, and then generative, linguistics became dominant in Britain in the mid-20th century, there were only a few who remained open to European influences (such as J. Lyons, S. Ullman, or Romance linguists, such as N. Spence, who contributed in particular to the debate about *langue* and *parole*). It was clear that the influence of the *Cours* was most likely to be acknowledged by linguists who challenged the mainstream, and indeed interest in Saussure was reawakened by Roy Harris's translation (1983) and by his sympathetic but not uncritical reading of the *Cours* (*Reading Saussure*) published in 1987. With increased research being conducted in the history of linguistics, Harris was one of a number of scholars from the United Kingdom, the United States, and Canada, such as E. F. K. Koerner, W. T. Gordon, J. Joseph, and G. Wolff, who raised historiographical and epistemological questions about the place of Saussure in 20th-century linguistics. On the wider front, with the reappraisal that was underway, it now seemed feasible to reconcile Saussurean linguistics with critical linguistics and critical theory, as for example in *Re-reading Saussure: the dynamics of signs in social life* (1997) by P. Thibault, editor of a multivolume edition of Saussure criticism (Routledge, forthcoming 2006).

It was in the United States that the major debates of 20th-century linguistics were to take place. Saussure himself wrote appreciatively of the American W. D. Whitney, particularly of his conception of language as a social institution, while at the same time criticizing him for not really envisaging language as system. Bloomfield in turn acknowledged a debt to Whitney in the preface to his first book, *An introduction to the study of language* (1914). Perhaps unsurprisingly, the only review that appeared in the U.S.A. of the *CLG* (second edition) was by Bloomfield in 1924. Bloomfield's review contained mitigated praise; he credited Saussure, along with others, with having elaborated the notion of the phoneme (*see* **Phoneme**), and acknowledged that Saussure lucidly set out "the theoretical basis for a science of human speech." Bloomfield claimed that the primacy of descriptive linguistics was already established, as was the social nature of language (though many would dispute that he himself took full account of this). He referred to the *langue/parole* distinction and to the concept of language as a system, but apparently without fully appreciating their centrality to Saussure's theory of synchronic linguistics. While Saussure will be accused by some future critics of structuralism of paying insufficient attention to meaning, for Bloomfieldian behaviorists his approach was too "mentalistic." Post-Bloomfieldians thus refer rarely to his work, with some exceptions, such as Twadell's recognition of his conception of the phoneme as relational and abstract.

Bloomfield would later say (in a letter written in 1945) that Saussure was present in every page he had written, but this was after an interest in European linguistics had taken a hold in the United States as a result of the arrival of intellectuals who fled Europe during World War II. To trace this strand of Saussurean influence on 20th-century linguistics, we have to return to Europe, where a young linguist named Karcevski went back to Russia after a year's stay in Geneva and took part in the Moscow Linguistic Circle, along with Jakobson and Trubetzkoy. As is well known, these two linguists moved westward and participated in the elaboration of the theses of the Prague Circle in the 1920s. Once in the United States during World War II, Jakobson became the single greatest disseminator of Saussure's ideas, both promoting and criticising them in lectures, such as a series entitled 'La théorie saussurienne en rétrospection' and 'Six leçons sur le son et le sens' (both at the émigré 'Ecole des Hautes Etudes Libres' in 1942), and in his publications. He approved of, and attributed to, Saussure and to Baudouin de Courtenay, the definition of the phoneme, but went on to develop his own theory of 'distinctive features.' He also drew on the Saussurean notions of syntagmatic and paradigmatic relations in his own studies of aphasia, and of metaphor. Where he departed from Saussure was on the arbitrary and linear nature of the sign, and on

the division between diachronic and what he saw as 'static' synchronic linguistics.

Perhaps as important as Jakobson's own work in the spread of Saussurean ideas was the work that he did in collaboration. He worked with Halle on distinctive features (cf. *Fundamentals of language*, 1956), and his study of Baudelaire's sonnet *Les Chats,* undertaken jointly with anthropologist Lévi-Strauss, marked the first structuralist analysis of literary language. Jakobson was one of the founders of the Linguistic Circle of New York, in whose journal *Word* one of the most significant outlines of Saussurean linguistics of that time was published (Wells, 1947), an article that became widely known through its inclusion in Joos (1957). Also active in New York was Martinet, a former pupil in Paris of Saussure's successors, and it was perhaps due to the influence of Martinet and Jakobson that an American translation of the *CLG* by Wade Baskin was published in 1959.

From the 1960s, the European 'rationalist' tradition was more compatible with the prevailing paradigm than it had been with the Bloomfieldian approach. The *CLG* was commented upon, for example, in *Cartesian linguistics* (1966), by Chomsky in his revisiting of the rationalist tradition. There was some common ground between *langue/parole* and Chomsky's competence/performance distinction and the idea that the main focus of linguistics should be *langue* or competence, although Saussure's notion of *langue* as a 'treasure' located in the mind of every speaker did not attribute to it the generative potential that characterized Chomsky's idea of 'competence.' While not claiming him as a major influence, Chomsky continued to refer to Saussure until recent publications (e.g., *New horizons in the study of language and mind,* 2000). Historians of linguistics in the United States, too, have mulled over Saussure's influence. These include Aarsleff (1982), who threw light on Saussure by considering him alongside certain other French thinkers such as the linguist Bréal; Falk (2004), who analyzed responses to Saussure in a broad range of American linguists' publications. Finally, where linguistics and semiotics come together, as in the work of Sebeok, it was not only Peirce who provided the impetus, but also Saussure's *Cours*.

Within France, Saussure's influence on colleagues and students was marked; among the latter, Passy and Grammont were responsible for the drawing up of the International Phonetic Alphabet. At the Ecole Pratique des Hautes Etudes, Saussure was succeeded by Meillet (*see* **Meillit, Antoine (Paul Jules) (1866–1936)**), whose contribution was primarily as a historical linguist; despite a superficial similarity in his contention that language was a social phenomenon, he referred here largely to factors operating on language from outside, as opposed to Saussure's idea of language as inherently social in nature. Nevertheless, Meillet considered himself to be a follower of Saussure, particularly in his conception of the focus of linguistic study: he was responsible for the famous final sentence of the *Cours* ("la linguistique a pour unique et veritable objet la langue envisagée en elle-même et pour elle-même"/'the only true object of study in linguistics is language considered in itself and for its own sake').

Guillaume (*see* **Guillaume, Gustave (1883–1960)**), Meillet's pupil and successor at the Ecole Pratique des Hautes Etudes, also considered himself a Saussurean, and he could in some respects be seen as taking over where Saussure left off. His view of language was of something dynamic and speaker-centered. He broadened *langue/parole* into '*langue-puissance*' (thus stressing the generative potential of language) and '*parole-effet*.' The aim of his '*psychoméchanique*' was to explain the passage from one to the other, i.e., the production of discourse. Guillaume has followers not only in France, but also in Belgium, and particularly Canada: his papers are held and edited at the 'Fonds Guillaume' at Laval University, and his work has been translated into English by Canadian linguists. It has been commented that his interest in the speaking subject made him the forerunner of Benveniste, who succeeded Meillet in his other post (a chair in comparative grammar at the Collège de France). Originally an Indo-Europeanist, Benveniste engaged with Saussure's ideas throughout his career, elucidating the notion of the arbitrary sign and promoting the concept of a system made up of a series of differences. In his own way, he too saw language as a dynamic and intersubjective phenomenon, and developed the theory of '*énonciation*,' an approach covering both pragmatics and speech act theory, which is perhaps the most buoyant and characteristic trend in contemporary French linguistics. If Benveniste has done more than Guillaume to disseminate aspects of what might be called French post-Saussurean linguistics, it is because his writing was more accessible, his distinction between *histoire* and *discours* had an important impact in literary analysis, and he was prominent in the development of semiotics in Europe, becoming the first president of the International Association for Semiotic Studies set up in 1969.

The links between French post-Saussureans and other European structuralists continued productively. Meillet's pupil, Martinet, mentioned above in connection with the review *Word,* had spent time in both Prague and Copenhagen before going to the United States and had introduced into France the work of Danish linguist Hjelmslev, whose 'glossematics' aimed to discover the underlying system of

elements that could recur in diverse combinations to produce language. The structuralist semantics of French linguist Greimas built heavily on both Saussure and Hjelmslev. Moreover, Hjelmslev's subdivision of Saussure's twofold distinction between form and content into a fourfold distinction provided the theoretical underpinning for Roland Barthes's categories of 'denotation' and 'connotation' (in, for example, *Mythologies*). While Barthes was more literary critic and semiologist than linguist, an overview of Saussurean trends in France would not be complete without a reference to this proponent of structuralism. Although replete with productive misreadings of the *Cours* and with a sometimes approximate understanding of linguistics, his work served as the intermediary through which Saussurean linguistics came to be regarded in the 1960s as the *science-pilote* for all the humanities.

Within Saussure's native Switzerland, his legacy has continued to be rich and varied (*see* **Geneva School of Linguistics after Saussure**). Most immediately, his own students Sechehaye and Bally engaged in research both marked by the *Cours* and different from it. The former adopted a psychological approach, and the latter promoted the place of the study of linguistic stylistics within *langue*. Saussure discussed the work of both in the *ELG*. Arguably, the most important contribution to Saussurean linguistics made by Swiss linguists has been in manuscript research, textual exegesis, and the general custodianship of the linguist's legacy. Since Saussure's death, conferences and volumes such as Amacker's *Linguistique saussurienne* (1975) kept alive his memory, as did the regular appearance of the *Cahiers Ferdinand de Saussure,* as well as a recently created Institut Ferdinand de Saussure. In 1957 Godel published the manuscript sources for the *CLG*, and then in 1968 and 1974, Engler's seminal comparison of all the available source notes appeared in two volumes. The most recently discovered manuscripts were edited by Engler and Bouquet (2002), and another volume is promised. This most recent volume both reinforces many of the ideas of the *Cours* and provides an insight into their gestation. It also shows a different Saussure: one convinced of the importance of situating linguistic analysis within a new philosophy of language, and one much more given to doubt and nuance than the style of the *Cours* would lead us to suspect.

Two final points: while the influence of Saussure in European linguistics is perhaps the easiest to chart, his legacy is worldwide, as is demonstrated by the interest shown in Saussurean linguistics in Japan (see, for example, the special issue of *Gengo 7(3)* [1978] and Tajima and Koerner, 1978). Secondly, although his ideas are of most pertinence to linguists and semioticians, they continue to be debated by researchers in a variety of disciplines, as they were in the mid-20th century. This is reflected in numerous ways, such as the recent publication of an article on Saussure in the review *Pour la science* (Bouquet, 2005) and the conferences of the 'Institut Ferdinand de Saussure,' founded in 1999, which have drawn together interested scholars in areas ranging from the cognitive and biological sciences to cultural studies.

Sayce, Archibald Henry, Reverend (1845–1933)

T C Christy, University of North Alabama, Florence, AL, USA

© 2006 Elsevier Ltd. All rights reserved.

Archibald Henry Sayce, comparative philologist, Orientalist, Assyriologist, and religious scholar, was educated at Oxford, where he was later professor of both Assyriology and comparative philology. He dedicated much of his research and linguistic abilities to determining the chronology and historical accuracy of information related in the Bible (cf., e.g., White, 1993: 2, 20). This was wholly in keeping with the dimensions of the discipline as laid out and practiced during the latter half of the 19th century, when comparative philology, still more the study of languages than the study of language *per se*, conventionally intersected the study of mythology, archaeology, religion, and history. In particular, Sayce is recognized for his contributions to the decipherment of Hittite hieroglyphic script and the Armenian of the Van inscriptions. His *Assyrian grammar* (1872) was the first English-language grammar of Assyrian (Assyrian Neo-Aramaic). As an important contributor to the science of language, Sayce is best remembered for his *Principles of comparative philology* (1874) and *Introduction to the science of language* (1880), both of which enjoyed multiple editions. The topics covered in his *Principles*—the relation of comparative philology to other disciplines (including comparative mythology and religion), the three stages theory of linguistic development, and the doctrine of roots, for example—mirror the 19th-century approach to the study of language, as found, for instance, in the works of Max Müller, to whom Sayce dedicated *Principles*, and William Dwight Whitney. Sayce's treatment of the evolution and practical applications of grammar in his article 'Grammar' (1910) is surprisingly modern: his analysis of the evolution of adverbs, prepositions, conjunctions and infinitives, for example, can be seen as foreshadowing the later study of grammaticalization.

Scaffolding in Classroom Discourse

S M Bortoni-Ricardo, University of Brasilia, Brasilia, Brazil

© 2006 Elsevier Ltd. All rights reserved.

The concept of scaffolding is grounded in the classroom discourse tradition and draws on two scholarly perspectives, developed in the realms of psychology and sociolinguistics, namely, the sociocultural theory of language and learning, as put forward by the Russian psychologist Lev S. Vygotskij, and the sociolinguistic approach to human interaction according to John Gumperz and others. These two strands of theory share a view of language as the foundation of learning and place emphasis on human actions as jointly constructed efforts.

Scaffolding is a metaphorical concept that refers to the visible or audible assistance that a more expert member of a culture can give to an apprentice.

Scaffold work is most often analyzed as an instructional strategy in the school domain, but it occurs in any social setting where socialization processes take place.

The term 'scaffolding' was introduced by the American psychologist Jerome Bruner (1983) whose main interest was in the institutional forms by which culture is passed on. A basic concept underlying his work is Vygotskij's zone of proximal development (ZPD). This zone lies in between what learners can do without assistance and the maximum they can do with the help of a more experienced partner (*see* **Vygotskii, Lev Semenovich (1896–1934)**).

According to Vygotskij's sociohistorical theory, external speech affects internal thoughts: the intrapsychological apprehension of knowledge is made possible by the interpsychological action.

Another concept underlying the rationale of scaffolds is contextualization cues as advanced in Interactional Sociolinguistics, i.e., "any feature of linguistic form that contributes to signalling to the participants whether communication is proceeding smoothly and how intentionality is being communicated and interpreted" (Figueroa, 1994: 113). Contextualization cues are conveyed through multiple linguistic and paralinguistic channels, such as prosodic features (pitch and tone, loudness, rhythm) and kinesics (facial decoration, eye gaze, smiles, frowns, and any other resources of the body idiom), which are important tools in the management of scaffold-like actions (*see* **Gestures: Pragmatic Aspects**). Hence the advantage of using a microethnographic methodology to segment any scaffolding episode into smaller interaction units.

In the tradition of classroom discourse, scaffolding is associated with teacher initiating and evaluating the students' responses within the IRE (initiation-response-evaluation) framework of classroom interaction. This can take the form of prefaces to questions, overlapping, backchanneling, comments, rephrasing, and expansion of pupils' answers that will provide them with an opportunity for reconceptualization (Cazden, 1988) (*see* **Classroom Talk**).

A basic feature of scaffolds is the establishment of a positive atmosphere between the participants whereby teachers support (scaffold) the students' enactment of a competent behavior. This can be done through ordinary actions that ratify the learner as a legitimate participant, such as listening to them, as

Scaffolding in Classroom Discourse

S M Bortoni-Ricardo, University of Brasilia, Brasilia, Brazil

© 2006 Elsevier Ltd. All rights reserved.

The concept of scaffolding is grounded in the classroom discourse tradition and draws on two scholarly perspectives, developed in the realms of psychology and sociolinguistics, namely, the sociocultural theory of language and learning, as put forward by the Russian psychologist Lev S. Vygotskij, and the sociolinguistic approach to human interaction according to John Gumperz and others. These two strands of theory share a view of language as the foundation of learning and place emphasis on human actions as jointly constructed efforts.

Scaffolding is a metaphorical concept that refers to the visible or audible assistance that a more expert member of a culture can give to an apprentice.

Scaffold work is most often analyzed as an instructional strategy in the school domain, but it occurs in any social setting where socialization processes take place.

The term 'scaffolding' was introduced by the American psychologist Jerome Bruner (1983) whose main interest was in the institutional forms by which culture is passed on. A basic concept underlying his work is Vygotskij's zone of proximal development (ZPD). This zone lies in between what learners can do without assistance and the maximum they can do with the help of a more experienced partner (*see* **Vygotskii, Lev Semenovich (1896–1934)**).

According to Vygotskij's sociohistorical theory, external speech affects internal thoughts: the intrapsychological apprehension of knowledge is made possible by the interpsychological action.

Another concept underlying the rationale of scaffolds is contextualization cues as advanced in Interactional Sociolinguistics, i.e., "any feature of linguistic form that contributes to signalling to the participants whether communication is proceeding smoothly and how intentionality is being communicated and interpreted" (Figueroa, 1994: 113). Contextualization cues are conveyed through multiple linguistic and paralinguistic channels, such as prosodic features (pitch and tone, loudness, rhythm) and kinesics (facial decoration, eye gaze, smiles, frowns, and any other resources of the body idiom), which are important tools in the management of scaffold-like actions (*see* **Gestures: Pragmatic Aspects**). Hence the advantage of using a microethnographic methodology to segment any scaffolding episode into smaller interaction units.

In the tradition of classroom discourse, scaffolding is associated with teacher initiating and evaluating the students' responses within the IRE (initiation-response-evaluation) framework of classroom interaction. This can take the form of prefaces to questions, overlapping, backchanneling, comments, rephrasing, and expansion of pupils' answers that will provide them with an opportunity for reconceptualization (Cazden, 1988) (*see* **Classroom Talk**).

A basic feature of scaffolds is the establishment of a positive atmosphere between the participants whereby teachers support (scaffold) the students' enactment of a competent behavior. This can be done through ordinary actions that ratify the learner as a legitimate participant, such as listening to them, as

the late Brazilian educator Paulo Freire has pointed out (Freire, 1997). The scaffolding assistance in the classroom can come from the teacher as well as from peers.

Scaffolding strategies are culture-specific and can vary largely across social networks, ethnic and cultural groups, and national communities.

Scaliger, Joseph Justus (1540–1609)

Y Gruntfest, Haifa, Israel

© 2006 Elsevier Ltd. All rights reserved.

A scion of the princely Veronese family della Scala and son of the prominent grammarian and humanist Julius Caesar Scaliger, J. J. Scaliger won renown as the greatest philologist and historian of his time.

Born in Agen, southern France, he was educated principally by his father, from whom he acquired a thorough knowledge of Latin. At the age of 19 he moved to Paris to study Greek, Hebrew, and Arabic. He later also mastered other Semitic and many modern European languages.

Brought up a Roman Catholic, he converted to Protestantism in his thirties.

Scaliger traveled extensively, partly on scientific missions and partly owing to the dramatic events of incessant religious wars. Luckily, on St Bartholomew's eve he happened to be in Lausanne, and he remained in Switzerland for two years teaching philosophy at the University of Geneva. His last 16 years were spent in The Netherlands as a professor at the University of Leiden. He was freed from lecturing and could devote all his time to his wide-ranging studies, his vast correspondence, and his instruction of students.

Scaliger began his scientific activities at the age of 25. In his critical editions of Latin and Greek authors, he substantially improved the philological methods of his Italian and French predecessors, basing his work on the collation of as many sources – manuscript and epigraphic – as possible and making amendments only if they were rigorously founded. Another important pursuit was a comparative investigation of ancient systems of dating. His summarizing work in this field, *De emendatione temporum*, became the foundation of scientific chronology. Scaliger's last substantial work, *Thesaurus temporum* (a critical edition of Eusebius's *Chronicle*), was another great achievement of his in historical chronology as well as in the technique of reconstruction of lost texts and in literary criticism.

In his best known linguistic work, *Diatriba de europaeorum linguis*, Scaliger, on the basis of obvious lexical and grammatical affinities, classified all main European languages. He discerned 11 families consisting of a mother-tongue (*matrix*) and off-shoots (*propagines*): four families were major (Latin, Greek, German, and Slavonic) and seven were minor (Albanian, Tartar, Hungarian, Finnish, Irish, Welsh, Basque). In a departure from earlier philology, Scaliger abandoned the monogenetic approach to languages, with Hebrew as the favored primeval tongue, and rejected the idea of genetic provenance of Latin from Greek. On the other hand, he abstained from the investigation of affinities between the mother-tongues, i.e., linguistic families, and denied any connections between them (*matricum vera inter se nulla cognatio est*).

J. C. Scaliger was born in Riva, Italy, and died in Agen, France. He read medicine at Padua and practiced it in Agen. Scaliger is best known for *De causis linguae latinae* (1540). He criticized the earlier grammarians and turned to the Aristotelian doctrine of four causes (material, formal, efficient, and final) and the Aristotelian categories. He construed his theory and philosophy of language on the basis of the Aristotelian physical model of natural laws applicable to natural phenomena, arguing that grammar was science, not art. Furthermore, he argued that grammar had to explain the use of language, and that its goal was to speak correctly – *recte loqui*. In Scaliger, 'concept' (thought) and 'object' equaled 'word,' with concept being a *speculum intellectus* of reality. Scaliger returned to the Modistae grammars' way of thinking, in many instances, but without acknowledging it. His thought was centered upon a single language, Latin. By adopting a scientific approach, he rejected the interpretative scholarship of the humanists who were gaining control over his object of study, and he made language and logic the mainstay of debate until the 19th century. His contemporaries were astounded by the severe criticism he addressed to them and resisted his thinking. He conceptualized grammar on the basis of spoken usage of language, describing written grammars as a secondary accident – an innovation for the time. His was a grammar of words, mainly. He started with the smallest parts, letters – *partes indivisibiles* – as the building blocks in the construction of larger units, the parts of speech. He was one of the first to include phonetics into the study of language. He introduced the concept of degeneration or corruption in language use from his classical standpoint. *De causis linguae latinae* contains the following parts: letters and sounds, syllables, words, nouns, verbs, pronouns, participles, prepositions, adverbs, interjections, conjunctions, syntax, and general methodological issues. Syntax is a minor part, regarded as a part of '*usus*', speech, hence ancillary. His idea of the arbitrariness of the sign was Aristotelian in nature. To Scaliger, concepts were the same in all languages, and it was convention only that established the meanings of words. Scaliger examined the classification of pronouns, verb tenses, and etymology (as general derivation). He borrowed the grammatical terminology (or metalanguage) from the *Modistae*. He preferred the term '*essentia*' *(essence)* to 'substance'. Scaliger referred to the following sources: Aristotle, Galen and Averröes, and ancient grammarians, including Priscian, Varro, Victorinus, Nigidius, Aullus Gellius, Diomedes, Quintilian, and Linacre. He was a fierce critic of many scholars. For instance, he wrote against Erasmus in 1531. He had a controversial approach in his *Poetices libri* . . . in which he placed Virgil above Homer. His thoughts were not disregarded by scholars and were often approached critically, e.g., by B. Buonmattei, M. Luther, Justus G Schottel, C. F. de Vaugelas, and G. Vico and others. His son, Joseph Juste Scaliger, was a humanist and a distinguished linguist. J. C. Scaliger wrote a rather fanciful autobiographical account of his own life. He is remembered for both the sharpness in his critical appraisals and his superb intellectual capabilities.

Scandinavia: History of Linguistics

A R Linn, University of Sheffield, Sheffield, UK

© 2006 Elsevier Ltd. All rights reserved.

This article focuses on the history of work on the Germanic languages of Scandinavia up to the turn of the 20th century. There was very little work of any significance produced prior to the 17th century. Two notable exceptions are the anonymous *First grammatical treatise* from mid-12th century Iceland and the 1586 *De Literis Libri Duo* by Jacob Madsen of Århus (1538–1586). The former, a highly subtle analysis of Icelandic phonology, stands at the beginning of a long and productive tradition of concern with orthographic reform in Scandinavia. The latter, an attempt to describe articulatory phonetics from a universal perspective, also exemplifies what would become a characteristically Scandinavian interest.

Much grammatical work of the 17th century was fueled by a patriotic desire to promote the national languages by demonstrating their richness. This is true, for example, of the 1651 *Grammaticæ Islandicæ Rudimenta* by Runólfur Jónsson (c. 1620–1654) and even more so of the work of the Danish 'Royal Philologist,' Peder Pedersen Syv (1631–1702). One of the results of this nationalist streak in grammar writing was the attempt to create a native set of grammatical terms to replace the Latinate terms, something we find in both Swedish and Danish grammars, and a task still occupying Scandinavian linguists two centuries later, most notably Rasmus Rask (1787–1832). While the 19th century may be regarded in the history of linguistics as *the* century of historical language work, 17th-century Scandinavian grammars exhibit a strong historical interest, as in the 1650 *Epitome descriptionis sueciæ, fenningiæ et subjectarum provinciarum* by Michaèl Wexionius Gyldenstolpe (1609–1670). Other Swedish scholars were occupied with work on Gothic (e.g., Georg Stiernhielm (1598–1672)) and the early history of the Scandinavian languages (e.g., Olof Verelius (1618–1682)).

The earliest grammars of Danish were reprinted in a six-volume set in the early 20th century (Bertelsen, 1915–1929). These are very mixed in terms of topics covered and of quality. *Introductio ad Lingvam Danicam* from around 1660 by Laurids Olufsen Kock (1634–1691), for example, is little more than a Latin grammar with Danish forms in the paradigms. The 1668 *Grammatica Danica* of Erik Eriksen Pontoppidan (1616–1678) is by contrast a substantial study of 426 pages, 100 of which cover syntax, and it was the first Danish grammar to accord syntax its proper place.

Two significant treatments of Icelandic appeared in the 18th century: *íslensk málfræði* by Jón Ólafsson of Grunnavík (1705–1779), from around 1737, and Jón Magnussón's (1662–1738) *Grammatica Islandica*. Although written in Latin, the latter work is the first description of Icelandic morphology on its own terms and is thus indicative of the greater sophistication of linguistic analysis in the 18th century.

The two questions dominating Swedish linguistic debate in the 18th century were standardization and lexical enrichment. The Swedish Academy of Science (Vetenskapsakademien) was founded in 1739, and it played an active role in the debate about the practical national linguistic questions that predominated at the time. In particular, it sanctioned the work of Abraham Magnusson Sahlstedt (1716–1776), whose prescriptive, usage-based *Swensk Grammatika* of 1769 was an admirably detached account of the structure of Swedish in an overheated climate. Unlike many of his contemporaries, he carefully distinguishes between the domains of the grammar and the lexicon. A theoretically more sophisticated grammar, praised by Noreen (1903), was the 1777 *Svenska Språket i Tal och Skrift* by Anders af Botin (1724–1790). The question of establishing a standard orthography dominated in Denmark too, although the

One of the results of this nationalist streak in grammar writing was the attempt to create a native set of grammatical terms to replace the Latinate terms, something we find in both Swedish and Danish grammars, and a task still occupying Scandinavian linguists two centuries later, most notably Rasmus Rask (1787–1832). While the 19th century may be regarded in the history of linguistics as *the* century of historical language work, 17th-century Scandinavian grammars exhibit a strong historical interest, as in the 1650 *Epitome descriptionis sueciæ, fenningiæ et subjectarum provinciarum* by Michaèl Wexionius Gyldenstolpe (1609–1670). Other Swedish scholars were occupied with work on Gothic (e.g., Georg Stiernhielm (1598–1672)) and the early history of the Scandinavian languages (e.g., Olof Verelius (1618–1682)).

The earliest grammars of Danish were reprinted in a six-volume set in the early 20th century (Bertelsen, 1915–1929). These are very mixed in terms of topics covered and of quality. *Introductio ad Lingvam Danicam* from around 1660 by Laurids Olufsen Kock (1634–1691), for example, is little more than a Latin grammar with Danish forms in the paradigms. The 1668 *Grammatica Danica* of Erik Eriksen Pontoppidan (1616–1678) is by contrast a substantial study of 426 pages, 100 of which cover syntax, and it was the first Danish grammar to accord syntax its proper place.

Two significant treatments of Icelandic appeared in the 18th century: *íslensk málfræði* by Jón Ólafsson of Grunnavík (1705–1779), from around 1737, and Jón Magnussón's (1662–1738) *Grammatica Islandica*. Although written in Latin, the latter work is the first description of Icelandic morphology on its own terms and is thus indicative of the greater sophistication of linguistic analysis in the 18th century.

The two questions dominating Swedish linguistic debate in the 18th century were standardization and lexical enrichment. The Swedish Academy of Science (Vetenskapsakademien) was founded in 1739, and it played an active role in the debate about the practical national linguistic questions that predominated at the time. In particular, it sanctioned the work of Abraham Magnusson Sahlstedt (1716–1776), whose prescriptive, usage-based *Swensk Grammatika* of 1769 was an admirably detached account of the structure of Swedish in an overheated climate. Unlike many of his contemporaries, he carefully distinguishes between the domains of the grammar and the lexicon. A theoretically more sophisticated grammar, praised by Noreen (1903), was the 1777 *Svenska Språket i Tal och Skrift* by Anders af Botin (1724–1790). The question of establishing a standard orthography dominated in Denmark too, although the

summative work of Jens Pedersen Høysgaard (1698–1773) eclipsed the practical writings of linguists such as Peder Schulz (1691–1773). Høysgaard's 1747 *Accentuered og Raisonnered Grammatica* and its companion volume of 1752, the *Fuldstændig Dansk Syntax*, are patriotic and steeped in the principles of General Grammar, which proved popular in Scandinavia until well into the 19th century. These two volumes endure among the monuments of Danish linguistics. The General Grammar approach was found particularly fruitful in teaching grammars, notably the anonymous 1761 *Dansk Donat*, the work of Niels Lang Nissen (1771–1845).

Icelandic began to arouse greater interest in the 19th century, both within and outside Scandinavia—a result of both the Romantic view of non-standardized vernaculars and its historical and comparative approach to language study. The groundbreaking work here was *Vejledning til det islandske eller gamle Nordiske Sprog*, by Rasmus Rask (Rask, 1811), who was the first to "impose order on the description of the Icelandic sound system and morphology" (Kvaran, 1996: 126). The last part of this grammar deals with what Rask calls "the Faroese dialect," the first published description of the grammar of Faroese. Publication in 1861 of the brief *íslenzk málmyndalýsing* by Halldór Kristján Friðriksson (1819–1902) made it possible for the first time to teach Icelandic schoolchildren about the structure of their own language in that language.

In 19th–century Sweden, two grammars dominated the education system: the 1824 *Svensk Språklära* by Anders Fryxell (1795–1881) and the 1832 grammar of the same name by Carl Jonas Love Almqvist (1793–1866). Fryxell consciously maintained the six-case system of nouns inherited from Latin, which strikes us as a peculiarly naïve and outdated *modus operandi*. However, he had a practical pedagogical motivation, namely, that the system of Latin grammar was the most widely known, and so, again clearly in deference to the General Grammar system of language teaching, it made sense to him to persevere with that system in describing Swedish. Almqvist's grammar was much more up-to-date in style and content, and included historical and comparative observations along with even (in the 3rd edition of 1840) a chapter entitled, "On the tongues of the Swedish countryside or the provincial dialects." A potentially influential grammar was the anonymous *Svensk Språklära* of 1836, which was championed by the Swedish Academy. However, its slavish commitment to describing Swedish as if it were Latin soon meant opprobrium was heaped upon it.

In Denmark as in Sweden, the influential treatments of the language during the 19th century were those written for use in the schools rather than descriptive accounts in the service of standardization and enrichment. Søren Niclas Johan Bloch (1772–1862) taught Rask at Odense Cathedral School and wrote a Danish teaching grammar in 1808, which underwent a thorough revision that produced the *Fuldstændig dansk Sproglære* of 1817. This is an extensive phonology and morphology that represents the culmination of 18th-century Danish scholarship, and it is explicitly indebted to Høysgaard and other 18th-century scholars. The next major departure was the work of Hans Henrik Lefolii (1819–1908), whose principles of grammar study brought Danish teaching in line with the general direction of linguistic thinking in northern Europe. Lefolii focused on sentence structure rather than the parts of speech in isolation. He also took the view that a grammarian should take into account the spoken language and its varieties as well as the history and evolution of forms being used. By the end of the 19th century, a more modern and extensive grammar was called for, and a prize competition set up by the Ministry of Education was won in 1890 by Kristian Mathias Mikkelsen (1845–1924), who wrote four different versions that represented an ambitious and comprehensive attempt to provide for the study and teaching of Danish.

The final section of Rask (1811) on Faroese was not a description of Faroese as such, but rather ranked Faroese as one of the "Nordic subdialects" (p. xlvi). Serious work on Faroese was taken up in the 19th century by Venceslaus Ulricus Hammershaimb (1819–1909), a priest and patriotic Faroe-islander. He published a grammar of the language in 1854 that appeared in a revised, standardizing form in 1891. The anthology of which this grammar formed a part also included a series of phonetic transcriptions made by Jakob Jakobsen (1864–1918), who was also responsible for the Faroese-Danish dictionary in the volume. Hammershaimb and Jakobsen did not agree on the means of standardizing the language, but Hammershaimb's etymologizing approach was sanctioned in 1895 by a new language council, and his system has remained the standard for Faroese up to the present time, with only minor modifications.

When Norway gained independence from Denmark in 1814, the standard written language of the new nation was still Danish and would remain so until the second half of the century. However, a number of reform proposals were advanced during this period, and two of them were pursued in a serious and committed fashion. The first centered on the work of Ivar Aasen (1813–1896), who travelled around Norway, with public funding, to survey the lexical and grammatical forms evidenced by the dialects. His work resulted in a descriptive grammar in 1848 and a

more overtly standardizing grammar in 1864 that had the programmatic title, *Norsk Grammatik*. Aasen also produced a dictionary and samples of this new written variety (initially, *Landsmaal* and later renamed *Nynorsk*). The second proposal to be followed through was that associated with the Norwegianization work of Knud Knudsen (1812–1895), which involved the wholesale importation into Danish of more Norwegian-looking lexical and grammatical forms and which led to the variety initially called *Riksmaal* and later renamed *Bokmål*. The leading Norwegian linguist of the day, Johan Storm (1836–1920), found fault with both reform proposals – Aasen's for being unnatural and Knudsen's for being distasteful. Both received official backing, however, and despite a century of language planning to bring them together, both have now been left alone by Norwegian language policy makers and exist side by side.

Although inevitably limited and superficial, this article does serve to bring out some of the defining characteristics of Scandinavian concern for the Scandinavian languages. This is a history of reform of one sort or another, with the 19th-century Norwegian case simply being one rather extreme example in a linguistic area willing to engage with its languages.

Danish

The standard dictionary of ancient Danish is Otto Kalkar's *Ordbog til det ældre danske sprog* (*Dictionary of the ancient Danish language*). It was published between 1881 and 1918 in five volumes, including a supplement. Originally, it was planned that the dictionary would include only those words from the period 1300–1700 that were unintelligible to Kalkar's contemporaries, but the entries eventually included all documented words from these four centuries. Preparations for a new historical dictionary, *Gammeldansk ordbog* (*Dictionary of Old Danish*), began around 1950 and the editing process commenced at the end of the 1990s. This dictionary is based on documents covering the period 1100–1515 and will thus cover a whole surviving corpus of the medieval Danish language. In 2004, entries for the letter G were being edited. In Copenhagen, at the Arnamagnæan Institute, editing is underway for an 11-volume *Ordbog over det norrøne prosasprog* (*Dictionary of Old Norse prose*); this work will cover the vocabulary of medieval Icelandic-Norwegian prose literature and is intended to replace Johan Fritzner's 19th-century *Ordbog over det gamle norske sprog* (*Dictionary of the Old Norwegian language*) (see later, Norwegian). Definitions in the new work are given in both Danish and English. So far, two volumes (entries up to Da) have been published, and a dictionary word list is available on the Internet.

The major source of the Danish vocabulary is the 28-volume *Ordbog over det danske sprog* (*ODS*; *Dictionary of the Danish language*), published from 1918 to 1956 and subsequently reprinted three times in smaller format. Since 1956, work on the *ODS* has continued, with the aim of adding further information about the Danish language during the period from 1700 to 1955. This has resulted in five additional volumes, *Supplement til Ordbog over det danske sprog*. A successor to the historical *ODS* is *Den Danske Ordbog* (*The Danish Dictionary*), a six-volume dictionary of contemporary Danish.

Retskrivningsordbogen (*Dictionary of orthography*), edited by the Danish Language Board, gives official spellings and inflections. In addition to providing an alphabetical list of entries, it describes the official Danish orthographic rules. This dictionary is also available online. *Den Danske Netordbog* (*The Danish Internet Dictionary*), developed and maintained by the Centre for Lexicography at the Aarhus Business College, is available online to the general public. Dictionary entries consist of the entry form of the lemma and grammatical information; they may also contain explanations of meaning and usage, synonyms, antonyms, examples, collocations, idioms, locutions, derivations, and compounds.

The largest modern Danish etymological dictionary is *Politikens etymologisk ordbog* (*Politiken's etymological dictionary*, published in 2000). It gives the origins of ~20 000 words central to the Danish vocabulary as well as personal names and placenames. An earlier work (*Dansk etymologisk ordbog. Ordenes historie* (*Danish etymological dictionary. The history of words*)) was first published in 1966, and the fourth and last edition in 1989 contained about 12 000 entry words.

Dansk sprogbrug: en stil- og konstruktionsordbog (*Danish usage: a dictionary of style and constructions*) was published in a new and revised edition in 1995. It has 13 000 entry words and covers around 64 000 constructions, set phrases, and locutions. Stylistic information is occasionally provided. There are two main Danish pronouncing dictionaries, *Den store Danske udtaleordbog* (*The unabridged Danish pronouncing dictionary*, 1991) and *Dansk udtale* (*Danish pronunciation*, 1990).

Denmark got its first important dialect dictionary, *Bornholmsk ordbog* (*Bornholmian dictionary*), in 1908. Dictionaries covering two other major dialects, spoken in the islands (mainly Sealand, Lolland-Falster, and Funen) and Jutland, are now being edited. *Ømålsordbogen* (*Dialect dictionary of the Islands*) is planned in 15 volumes, with the first several volumes being published in 2004. The dialect dictionary for Jutland, *Jysk ordbog*, is published electronically on the Internet as the editing proceeds; the entries A–He were accessible by 2004.

Norwegian

Johan Fritzner's *Ordbog over det gamle norske sprog* (*Dictionary of the Old Norwegian language*), published in three volumes from 1886 to 1896, is still a major reference work in Old Norse philology; a fourth supplement volume was published in 1972. Another classic work, the one-volume *Norrøn ordbok* (*Old Norse dictionary*), with ~40 000 words, has come to be the standard dictionary of Old Norse in Scandinavia; this volume has been published in several revised and enlarged editions since the original publication, *Gamalnorsk ordbok* (*Old Norse dictionary*), first appeared in 1909.

The first major work of Norwegian lexicography was Ivar Aasen's pioneering *Ordbog over det norske folkesprog* (*Dictionary of Norwegian dialects*); first published in 1850, an enlarged and revised edition, with the more general title *Norsk ordbok* (*Norwegian dictionary*), was published in 1873. In both editions, Danish is the metalanguage. This dictionary, with its precise definitions and word localizations, formed the basis of the vocabulary of Landsmål (called Nynorsk since 1929), one of the two official languages of Norway. A supplement of 40 000 dialect words was published by Hans Ross in 1895.

The first major dictionary of Norwegian in the 20th century, *Norsk riksmålsordbok*, was published in four volumes from 1937 to 1957, with two supplemental volumes appearing in 1995. This work is a dictionary of the literary language or Riksmål (called Bokmål after 1929), which is the other official language of Norway. In 1930, the first steps were taken toward producing the most comprehensive Norwegian national dictionary ever. This project, *Norsk ordbok* (*Norwegian dictionary*), with the informative subtitle *Ordbok over det norske folkemålet og det nynorske skriftmålet* (*Dictionary of Norwegian dialects and the Nynorsk literary language*), is planned to be completed in 12 volumes in 2014 and to include ~300 000 words. As of 2005, five volumes have been published. The editorial decision to include both dialect and literary words is a unique feature. Much of the source material is available on the Internet, including the metadictionary, the complete card index, and the Nynorsk text corpus.

There are no standard dictionaries of Bokmål and Nynorsk that give official spellings and inflections, but numerous editions are examined and approved by the Norwegian Language Board. The most widely used general dictionary for Nynorsk is *Nynorskordboka* (third edition in 2001; 90 000 words). There is also a parallel edition, *Bokmålsordboka* (third edition in 2005; 65 000 words), for the users of Bokmål. Both dictionaries are available on the Internet. A controversy over Norwegian linguistics has promoted the publication of some Riksmål dictionaries with conservative spelling and inflectional variants not officially accepted; one of these works, *Norsk ordbok med 1000 illustrasjoner* (*Norwegian dictionary with 1000 illustrations*), has ~60 000 entries.

Standard etymological dictionaries published by Falk and Torp between 1903 and 1919 remained unrivalled until Bjorvand and Lindeman published *Våre arveord* in 2000; this work is a comprehensive collection of articles on the etymology of native words. The general acceptance of linguistic variation in Norway has resulted in few pronunciation dictionaries. One such dictionary for Bokmål, *Norsk uttaleordbok* (*Norwegian pronunciation dictionary*), was published in 1969.

Swedish

The vocabulary of medieval Swedish can be found in Knut Fredrik Söderwall's *Ordbok öfver Svenska Medeltids-språket* (*Dictionary of the medieval Swedish language*). This two-volume dictionary was first published in 1884–1918. Supplementary volume, *Supplement till Ordbok öfver svenska medeltidsspråket 1–2*, was published in 1925 and used in 1973. An electronic version of the two original volumes is available on the Internet.

The central project in Swedish lexicography is *Svenska Akademiens ordbok* (*The dictionary of the Swedish Academy*). Since the first volume appeared in 1898, 31 volumes have been published, covering approximately 436 000 entries, up to the entry *talkumera*. Articles contain information on pronunciation, definitions, and etymology. The dictionary is available on the Internet. *Svenska Akademiens ordlista* (*The wordlist of the Swedish Academy*) provides the unofficial norm for spelling and inflection in Swedish. The entries also give information on pronunciation, the structure of compound words, and the definitions of less common words. The 11th edition was published in 1998, with around 120 000 entries. This edition and two earlier ones are available on the Internet.

Svenska språknämndens uttalsordbok (*Pronouncing dictionary of the Swedish Language Board*), published in 2003, presents recommended standard pronunciations of 67 000 words in the central vocabulary of contemporary Swedish, as well as loanwords and technical words. In addition to transcriptions of the entry words based on International Phonetic Association standards, the articles give information on use and style. Another useful work, *Ordbok över konstruktioner och fraser* (*Dictionary of constructions and phrases*), also published in 2003, is edited by staff members at the Swedish Language Board. It covers grammatical constructions, more or less set phrases, and expressions and locutions in present-day Swedish. The dictionary contains approximately 85 000 constructions and more than 70 000 illustrating examples based on authentic texts.

There are two main Swedish etymological dictionaries, both first published in the 1930s. The most comprehensive work is Elof Hellquist's two-volume *Svensk etymologisk ordbok* (*Swedish etymological dictionary*); originally published in 1922, third edition in 1948. The first edition of Elias Wessén's *Våra ord: kortfattad etymologisk ordbok* (*Our words: Concise etymological dictionary*) was published in

1932; the second edition came out in 1973. Both dictionaries have been reprinted several times.

The most ambitious project among Swedish dialect dictionaries, *Ordbok över Sveriges dialekter* (*Dictionary of Sweden's dialects*), began in 1991. By 2004, the published material covered the entries A–back. The articles contain a pronunciation guide, definitions, and usage of the entry words, as well as occasional etymologies and literary references.

Swedish is the first language of approximately 6% of the population in Finland and has official status. There are some differences between Swedish in Finland and Swedish in Sweden, mainly in pronunciation, but also in vocabulary and grammar. *Finlandssvensk ordbok* (*Finno-Swedish dictionary;* third edition published in 2002) treats special Finno-Swedish words and phrases. *Ordbok över Finlands svenska folkmål* (*Dictionary of Finland's Swedish dialects*) is planned to be published in seven volumes. By 2004, three volumes had been published, covering the vocabulary up to 'kyss.'

Icelandic and Faroese

A comprehensive Old Icelandic-English dictionary was initiated by Richard Cleasby and was completed by Guðbrandur Vigfússon in 1874. A second edition with a supplement was published in 1957. The most widely used Icelandic dictionary today is *Íslensk orðabók* (*Icelandic dictionary*); reissued in 2000, this work has been revised and enlarged to contain 90 000 entries since the first edition appeared in 1963. The most recent and comprehensive Icelandic etymological dictionary is Ásgeir Blöndal Magnússon's *Íslensk orðsifjabók*, published in 1989, with 25 000 entries. The only comprehensive Faroese monolingual dictionary is *Føroysk orðabók* (published in 1998), with 65 600 entries.

Schema Theory: Stylistic Applications

P Stockwell, University of Nottingham, Nottingham, UK

From Scripts to Schemas

There have been several approaches in the recent history of linguistics to account in a principled way for the fact that meaningfulness is a product of both text and context. That is, meaning cannot be explored by an examination only of text and textual structures, but inevitably has to involve a discussion of the perceptions, selections, omissions, and enrichment provided by an observing consciousness. When linguistics as a discipline expanded exponentially in the middle of the 20th century, making claims for its scientific rigor as a rule-governed paradigm, structuralist and formalist linguists were understandably reticent to stray too far into psychology.

This is not to say that linguists have ignored the problem. Many semantic models – even thoroughly formalized ones – have included an element of the receiver's 'encyclopedic knowledge' as a means of explaining phenomena such as inferencing, perceived presupposition, implicature, and apparent leaps of intuition. The fact that text underdetermines the meanings that receivers experience is the simplest demonstration that this extraneous knowledge is being drawn upon to flesh out the bare bones of linguistic denotation. Bluntly, linguistic semantics alone cannot account properly for the richness of meaning.

The problem for linguistics in its rule-governed paradigm was establishing the principles that could explain which specific part of a receiver's potentially huge store of knowledge is drawn down on any particular occasion. The problem is even more acute for stylisticians interested in the operation of discourse in its social situation, and often concerned with how meaning is negotiated and developed beyond the text itself. It has long been recognized that language exhibits 'conceptual dependency': text underdetermines the meaning that it is intended to convey and that is actually derived from the utterance. Speakers and hearers rely on their shared assumptions, environment, and wider knowledge to convey a richness of communication without enumerating in excruciating detail every facet of the message. People tend only to be aware of this process in vague and intuitive terms.

One of the first theoretical developments to achieve some success was 'schema theory.' The idea that humans use a schematized representation of detailed experiences as a tool for negotiating similar experiences had a tradition going back to Kant, and the notion was operationalized in a series of experiments by Bartlett (1932) conducted in the early part of the century. However, modern schema theory arose out of experiments at the end of the 1960s, aiming towards creating artificial intelligence, and so arrived with appropriate scientific credentials to be accepted within linguistics. Machine intelligence researchers quickly realized that for computer-based minds to possess language, they needed to have a sense of a contextualizing world that would offer experiential connections between referents and processes. The artificial language user would need a limited set

From Scripts to Schemas

There have been several approaches in the recent history of linguistics to account in a principled way for the fact that meaningfulness is a product of both text and context. That is, meaning cannot be explored by an examination only of text and textual structures, but inevitably has to involve a discussion of the perceptions, selections, omissions, and enrichment provided by an observing consciousness. When linguistics as a discipline expanded exponentially in the middle of the 20th century, making claims for its scientific rigor as a rule-governed paradigm, structuralist and formalist linguists were understandably reticent to stray too far into psychology.

This is not to say that linguists have ignored the problem. Many semantic models – even thoroughly formalized ones – have included an element of the receiver's 'encyclopedic knowledge' as a means of explaining phenomena such as inferencing, perceived presupposition, implicature, and apparent leaps of intuition. The fact that text underdetermines the meanings that receivers experience is the simplest demonstration that this extraneous knowledge is being drawn upon to flesh out the bare bones of linguistic denotation. Bluntly, linguistic semantics alone cannot account properly for the richness of meaning.

The problem for linguistics in its rule-governed paradigm was establishing the principles that could explain which specific part of a receiver's potentially huge store of knowledge is drawn down on any particular occasion. The problem is even more acute for stylisticians interested in the operation of discourse in its social situation, and often concerned with how meaning is negotiated and developed beyond the text itself. It has long been recognized that language exhibits 'conceptual dependency': text underdetermines the meaning that it is intended to convey and that is actually derived from the utterance. Speakers and hearers rely on their shared assumptions, environment, and wider knowledge to convey a richness of communication without enumerating in excruciating detail every facet of the message. People tend only to be aware of this process in vague and intuitive terms.

One of the first theoretical developments to achieve some success was 'schema theory.' The idea that humans use a schematized representation of detailed experiences as a tool for negotiating similar experiences had a tradition going back to Kant, and the notion was operationalized in a series of experiments by Bartlett (1932) conducted in the early part of the century. However, modern schema theory arose out of experiments at the end of the 1960s, aiming towards creating artificial intelligence, and so arrived with appropriate scientific credentials to be accepted within linguistics. Machine intelligence researchers quickly realized that for computer-based minds to possess language, they needed to have a sense of a contextualizing world that would offer experiential connections between referents and processes. The artificial language user would need a limited set

of knowledge, and a principled, programmable means of drawing down the appropriate elements of that set.

Early suggestions involved an extension of work in visual perception by, for example, Minsky (1975, 1986). The scene that a mind sees is far richer than the signals that the eyes see. Objects are foregrounded and backgrounded, common objects are treated conceptually as unitary features, the mind can understand that objects that disappear behind other objects maintain their conceptual integrity and will emerge when the occluding object has passed on. Relationships that are not actually seen are inferred and filled into the 'frame' of visual perception (Fillmore, 1985). The analogue of the frame in language is providing the artificial mind with a 'script': a predictable sequence of events with linguistic input.

The classic example is the 'restaurant script,' which maintains the rules of restaurant interaction. The restaurant script includes an inventory of commonly encountered objects, such as tables, cutlery, glassware, chairs, menus, wine lists, and their appropriate uses. It also includes objects such as the waiter, the chef, other diners, and sets of utterances they are likely to make. The restaurant script maintains the appropriate terms to be used, allows me to predict what the other person will say, and narrows down the possibilities for my replies. In short, the script represents a set of procedures that will allow me to get what I want.

Scripts are organized towards plans and goals, therefore. In fact, in the work of Schank and Abelson (1977), where the restaurant script first appeared, scripts are described as developing out of 'plans.' These are generalized conceptual procedures such as 'socializing,' 'engaging in a transaction,' or 'moving to a new location.' When a certain subtype of plan is repeated and becomes routine in experience, it becomes relatively fixed as a script. Plans and scripts arise in turn out of higher level 'goals,' which are very general aims and objectives carried by individuals, such as satisfaction goals, achievement goals, preservation goals, and so on. Plans and goals are the conceptual tools we use to negotiate new situations, and we adapt our existing scripts when we encounter situations that are similar but subtly different from recognized existing scripts.

In Schank's later work (1982a, 1982b, 1984, 1986), scripts, plans, goals, and their contents are regarded not as entirely fixed structures but are conceptualized as emerging from a process of assembly in the course of discourse processing. Their configuration is dynamic, responding to the environment at hand. Similarly, the detail of the script depends on the stylistic input as well as the particular experiential base of the receiver: in the restaurant script, for example, the recognition of a rude waiter or poor service will be identified largely by the politeness discourse used. In this way, the theory also encompasses pragmatic matters. As the notion of scripts became more dynamic and less fixed, and the notion was used by other researchers in stylistics and sociology, they came to be retermed 'schemas.' Schemas are what allow people to manage all situations that are familiar, not so familiar but similar to past experience, and unfamiliar but vaguely recognizable; they also offer a template for managing apparently alien and unexpected situations that can then be adapted and perceived in terms of existing knowledge. The rest of this article will use the terms 'scripts' and 'schemas' interchangeably to refer to the same phenomenon, though some linguists prefer to keep the sense that scripts are fixed and schemas are dynamic notions.

Operationalizing Schemas

So far, the notion of schemas is relatively uncontentious, since there is a mass of empirical as well as anecdotal and intuitive evidence that some sort of schematized understanding is a fundamental characteristic of human discourse processing. However, disagreement occurs as soon as the notion is 'operationalized': that is, rendered into a more detailed procedure that can actually be applied in analysis. This section will present the detail of schema theory's analytical framework, before going on to consider some complicating factors in the next section.

Clearly, individuals are not born with a ready-made set of schemas for their culture. These have to be learned either by experience or vicariously through teaching, mythology, or projected situations such as literary fiction, jokes, proverbs, and social rules. Later in life, schemas are built either by extending the detail in an existing schema, or by adapting several existing schemas to create a newly configured schema. In both cases, there is a question over where the first schema comes from, and it may be that human brains are 'hardwired' with the ability to schematize at the most abstract level, and life experience fills in those generalized frameworks with detailed and usable schematic knowledge (de Beaugrande, 1987; Spiro, 1982). The question of individual mental origins, however, remains debatable.

The fact that schemas accumulate complexity through life means that they become multifaceted. Restaurants can be encountered in a range of types: smart metropolitan cafe-bars; countryside pubs that serve food; corporate burger chains and fast-food trailers; Italian, Mexican, Thai, Chinese and French

restaurants – all with their different sets of elements and procedures for behaving appropriately. Rather than creating a new schema to deal with each of these subtypes, schema theory maintains that the basic schema has different 'tracks' through the schema. In other words, there are certain elements that are common to the restaurant schema (such as being served food prepared by someone else, sitting down, paying a bill or check) but different manifestations of these elements.

This existence of basic components does not mean, however, that schemas can be articulated in terms of a set of primitive elements that are core members of the schema. Even those previous few examples can be disrupted: there are restaurants in which you select and grill food yourself, there are restaurants in which you stand or kneel to eat, and there are restaurants operated by charitable organizations in which the diners do not pay, for example. This looseness of schema theory is partly handled by the notion of 'tracks' through basic schemas, but the difficulty of being able to formalize schematic elements could be seen as a problem.

Schemas like the restaurant example, that are defined by the location in which they take place, are 'situational' schemas. Drawing the appropriate schema into mental play in these cases is often a matter of being in the situation: it is self-evident that the restaurant schema is likely to be running if you walk into a restaurant. Other schemas depend on enacting social or individual roles: these are 'personal' schemas. We instantiate a personal schema in order to enact the role of being a passenger at an airline ticket desk, or to manage the appropriate conversation to have as a student, or to greet a potential business associate, for example. While personal schemas are of course also socially and culturally determined, there is a relatively greater degree of willful choice in performing a personal schema than in engaging in a situational schema.

Thirdly, 'instrumental' schemas maintain our knowledge of how to do things: switching on a room light, driving a car, being able to read, and so on. These schemas are intuitively regarded as skills that have been learned through life. Although situational and personal skills are also learned, most people have a sense that instrumental schemas represent useful knowledge. Situational schemas tend to be a matter of civilization and culture, and personal schemas tend to be a matter of personality and social adeptness.

Knowing exactly which schema to draw on in a particular circumstance is determined by recognizing certain 'headers' that are likely to instantiate the schema. The most obvious of these are 'internal conceptualization headers': references to elements, actions, or roles from inside the script and that are strongly associated with that schema are likely to activate the schema in general. If you are told a story that begins with someone ordering food from a waiter, the restaurant schema is highly likely to be drawn down immediately. The storyteller can then be fairly confident that the situation of the restaurant will be sufficiently rich in your head to be able to refer to elements in the restaurant without having to introduce them laboriously. Definite reference can be made ('the waiter arrived,' 'the food was cold,' 'the tip was generous') without you becoming confused ('oh, was there a waiter?,' 'what food?,' 'you didn't say you left a tip') and without the storyteller having to set out all of the objects in the situation ('there was a waiter,' 'some food was brought,' 'we left a tip'). Internal conceptualization headers are often the essential elements if the circumstance is being conveyed vicariously.

Clearly, in firsthand experience, you are much more likely to instantiate a particular schema during some preparatory period: it is rare that we come to consciousness already embedded in a situation, as we do in projected experiences like literary fiction. 'Precondition headers' are references that act as a precondition for the application of a script. Hearing someone say, 'I'm hungry,' and someone else adding 'I've just been paid,' the restaurant schema is likely to be drawn down. Alternatively, 'instrumental headers' such as, 'He booked a table over the telephone,' serve to highlight actions that are a means towards the realization of a restaurant script. Lastly, 'locale' headers that refer to the usual setting in which the schema applies are likely to instantiate the particular script.

These four types of headers are often combined, and in fact, it seems to be the case that at least two headers are required to get a schema up and running. Single headers ('I'm hungry') are not usually enough to instantiate the restaurant schema on their own ('I'm hungry, but I need to get on with this job'). If a schema is briefly brought to mind in this way, but then not developed further, this phenomenon is known as a 'fleeting script.' Similarly, there seems to be a factor of centrality or strength required in the header to activate a schema: prototypical elements of the restaurant script (waiters, menus, bills) are likely to be stronger headers than elements that are less prototypical or not exclusive to the restaurant script and are shared with other schemas (tables, plates, candles).

So far, the notion of the schema has been rather general. However, schema theory offers a sense of the schema as a rich conceptual environment. The framework includes a set of categories to operationalize the

detailed elements and processes involved in running a schema. There are various kinds of 'slots' that are associated with any particular script and are assumed to be in operation when the schema is running. These are 'props,' 'participants,' 'entry conditions,' 'results,' and the 'sequence of events.' The props of the restaurant schema consist of all the objects and paraphernalia that usually exist in a restaurant. The activation of the schema means that all these props are available for reference without preamble or laborious introduction, and in fact, our expectation of certain prototypial props is often so strong that a restaurant that lacks any of them is remarkable and requires explanation. A restaurant without tables, without a menu, or even without food would cause confusion unless there were some explicit reason given.

Similarly, schemas carry their cast list of characters in the form of expected 'participants.' There is no need to say, 'there was a waiter,' in the restaurant schema, since this core participant is already available for reference once the schema is running. In fact, 'self-service' restaurants are more likely to require that modifying explanation. So strong is the inventory of props and participants in a schema that the word 'but' in the following sentence seems entirely natural:

> We went into the restaurant but it was empty.

while the following sentence seems odd:

> We went into the restaurant but there were waiters and tables there.

Aside from the preparatory headers that instantiate a schema, the schema itself will often have a narrativized sequence that is normal and expected. The restaurant schema typically has 'entry conditions' involving walking into the restaurant, sitting down, and ordering food. Completing the restaurant schema has 'results' that are usually satisfaction, or food poisoning, or going home. And there is an expected 'sequence of events' within the narrative of the schema. Even nonsituational schemas (personal and instrumental scripts) possess typical props and participants, and are often conceptualized in narrative terms with opening, sequential, and resulting features.

Stylistic and Fictional Applications

It should be clear from the account above that schema theory can be used to provide a means of understanding everyday, commonly encountered experiences, where it offers an explanation for facts from human cognitive adaptability to the use of definite reference in specific circumstances. However, much daily interaction exhibits displaced discourse, in the sense that talk and writing can be about circumstances not here and now but past, imagined, hypothesized, occurring elsewhere, and drawing on the experience of other people. Fiction, in particular, offers a special case that challenges the capacity of schema theory, and literary stylisticians have tried to adapt schema theory into a schema poetics in order to address the cognitive problems of fictionality.

One problem for a schema poetics is that schema theory is based on commonality, whereas high quality literature tends to be based on uniqueness. That is, the ability to 'defamiliarize' the world and show it refreshed is sometimes regarded as the hallmark of good literature. Cook (1989, 1992, 1994) has developed a means within schema theory of accounting for this apparent discrepancy. He argues that most everyday discourse draws relatively straightforwardly on existing script knowledge, and is thus confirmatory and 'schema preserving.' In fact, common schemas are even reinforced in the process of being seen to work. He points to much advertising discourse that relies on stereotypical understanding as being schema reinforcing, however stylistically creative and apparently 'literary' it might seem.

By contrast, novel, startling, striking, or very moving literary works, it is argued, can potentially disrupt the reader's settled schematic worldview. Such experience offers a challenge to existing knowledge structures. One way in which these disruptions can be resolved is by 'schema accretion' (Rumelhart, 1975, 1980, 1984) – by the enlargement and complexification of the schema in question. In other words, existing schemas become richer either with a greater number of props and participants or by evolving more tracks through different narrative possibilities. This enriching is the experience of enhanced understanding arising from an encounter with a challenging discourse (such as, but not restricted to, literature). Alternatively, the reader of literature might experience a radical defamiliarization of their worldview, and is termed 'schema refreshment' (Cook, 1994) or 'tuning' (Rumelhart and Norman, 1978).

These uses of schema theory to discuss literariness distinguish between three types of schema occurrence: 'world schemas,' 'text schemas,' and 'language schemas' (Semino, 1997). World schemas are concerned with conceptual content, like the restaurant script discussed above. Text schemas represent the ways in which we expect to encounter these content-scripts in terms of their sequencing and structural organization. Our language schemas provide us with expectations of the appropriate linguistic and pragmatic features in which the world is articulated. The last two of these schema types – text and language schemas – constitute expectations about the discourse

patterning of experience. Crucially, they fill in the missing link of classical schema theory: the stylistic texture. Returning again to the restaurant schema, there are dozens of ways in which the restaurant manager might greet me at the door, but the world schema alone will not provide me with an expectation of what form of words might be used. However, the language schema I have associated with certain restaurant types will narrow down the possibilities, so that I will have my interactive toolkit of possible and appropriate utterances ready to go.

Disruptions in our expectations of sequence and style together constitute 'discourse deviation' (Cook, 1994), which will result either in confusion or, if resolved, will offer possibilities for schema refreshment. Schema theory thus offers the stylistician a neat way of connecting conceptual content with linguistic texture.

There are, of course, many questions that remain for schema poetics to answer. In focusing on the psychological processing of one of the participants, schema theory downplays the social and interactional aspects of discourse (see Edwards, 1997 for such criticism). For my schema to be efficient, my interlocutor must be running the same, or at least a very similar schema. Presumably this assumption must mean that they share my formative experiences. What happens if our respective experiences have been radically different? You might expect a waiter to have a much richer restaurant script than I do, yet I usually have little problem communicating in restaurants. Furthermore, my schema does not tell me exactly what the other person is going to say, though the extension of the theory into text and language schemas deals with this vagueness to some extent. Schema theory has a flavor of consensual social relations about it; what happens when interlocutors are being deliberately obstructive, obscure, or antagonistic?

Another question concerns the prospects for formalizing schema theory. Many schema poetic applications (Tsur, 1992: 207–243; Culpeper, 2001; and Cockcroft, 2003) suggest domains as schemas that are convincing in context but seem rather improvised or makeshift. In Culpeper's ingenious work on schema theory and characterization in Shakespeare, for example, he describes the effects of running a 'shrew schema' in a reading of the play *The taming of the shrew*. However, I'm not sure that I either have a shrew schema at all, or whether the poor shrew knowledge that I have might not be a track through a more general and imprecise rodent schema. Do I have a general 'play schema,' with a Shakespearean track, or in fact, do I have a 'Shakespeare schema,' or even a schema for individual plays? The last proposition seems unlikely, and in fact would rob schema theory of its claim to generalizability, but schema theory could do with a principled way of establishing which schemas are basic and which are superordinate and subordinate.

It might be argued (Stockwell, 2003) that the problems that remain in schema theory make it difficult to use as a sociolinguistic framework in which social and cultural factors, power asymmetries, and a principled set of fixed templates are needed to account for face-to-face interaction. However, many of the recent advances and innovations in schema theory have been developed by stylisticians in relation to the literary context, as a sort of schema poetics. In this context, the element of displacement between the discourse participants (most literary authors are dead and remote from their readers) leaves much of the foundations of schema theory intact. Schema poetics remains a convincing way of accounting for the fact that different readers produce different interpretations of the same text, while shared experience generates broadly shared readings.

Scherer, Wilhelm (1841–1886)

M Pierce, University of Michigan, Ann Arbor, MI, USA

© 2006 Elsevier Ltd. All rights reserved.

Although his life was relatively short, Wilhelm Scherer made substantial contributions to both Germanic linguistics and German literary studies. Scherer was born on April 26, 1841, in Schönborn, Austria. In 1858 he enrolled at the University of Vienna to study Germanic philology; in 1860, after clashing with one of his teachers, he left Vienna for Berlin, where he established a close relationship with Jacob Grimm and studied with a number of prominent scholars of the time. He made his first impression on the scholarly world when he collaborated with his Berlin teacher Karl Müllenhoff on an edition of early German prose and poetical texts (Müllenhoff and Scherer, 1864). Scherer was responsible for editing the prose texts and some of the poems; his work on this project was excellent, especially considering his youth and inexperience. His portion of this work earned him a doctorate (1862) and a *Habilitation* (1864), both from Vienna. In 1864 he also began his teaching career in Vienna, becoming *ordentlicher Professor* there in 1868. In 1872 he left Vienna for Strassburg, joining the faculty of the newly established German university there. (Schmidt, 1887 suggests that this change was at least partially motivated by Scherer's intense feeling of German nationalism.) Scherer taught in Strassburg for five years before accepting a position at the Humboldt University in Berlin, where he remained until his death in August of 1886.

Scherer's contributions to *Germanistik* are manifold. He contributed significantly to biographical studies, preparing biographies of his friend Jacob Grimm and his teacher Karl Müllenhoff, as well as various shorter biographical sketches. (A planned biography of Goethe was unfortunately never completed.) Scherer also published substantially on German literature; his contributions to this field include his early work with Müllenhoff cited previously, as well as books on medieval German poetry and the history of German literature (Scherer, 1875, 1880–1883). His main contribution to Germanic linguistics is his *Geschichte der deutschen Sprache* (Scherer, 1868). While this book was not universally applauded when originally published, it remains a landmark in Germanic linguistics. Scherer also prepared new editions of Jacob Grimm's *Deutsche Grammatik*, accompanied by detailed prefaces (e.g., Grimm, 1869), and published a number of shorter essays and reviews on linguistic topics. The newest edition of Scherer's most famous book (Scherer, 1995) should help to maintain awareness of Scherer's work.

Schizophrenia and Language

C Marvel, University of Iowa, Iowa City, IA, USA

Overview of Language Deficits

Schizophrenia is a psychiatric disorder that affects approximately 1% of the population worldwide. Symptoms typically involve an array of perceptual, emotional, and cognitive impairments, including language. The term 'disorganized speech' has been used to describe a broad range of abnormal verbal communication behaviors observed in patients with schizophrenia. Many clinical researchers view such language deficits as a reflection of thought disturbance and, consequently, as a formal thought disorder (FTD). The expression of speech is not impaired, as in aphasia. Rather, a patient's speech is thought to represent an underlying disorganized thought process in which loose associations are woven into the conversation (see Critchley, 1964). The issue of whether language impairment in schizophrenia reflects an underlying disruption in thought processes or is a true disorder of speech is open to debate (see Chaika, 1982). It is nevertheless uncontroversial that linguistic disturbances in schizophrenic speech follow a general pattern of anomalies that are related to the presence of FTD. Therefore, this article discusses linguistic processing deficits in schizophrenia within the context of thought disorder.

Formal thought disorder is divided into positive and negative types. Positive FTD is associated with speech that is fluent and detailed; however, communication of ideas is poor. In contrast, negative FTD reflects an impoverished thought process in which speech is nonfluent or barren of content. The primary symptoms of FTD have been defined by Andreasen (1979) and are outlined in **Table 1**. This classification system has become a standard tool for characterizing language deficits in many psychiatric disorders.

Clinical Observations

Clinicians identify language deficits in schizophrenia through verbal communication with the patient. When FTD is present, the listener may find the dialogue hard to follow. Sometimes the direction of a patient's conversation dissolves as ideas become obliquely related. For example, a patient may start speaking on a particular topic but quickly digress to an irrelevant topic. Alternatively, a patient may answer a question at length in a seemingly normal manner, yet the response itself provides little substantive information. An interesting feature of disorganized speech, however, is that the syntactic and grammatical components of language remain intact, with the exception of relatively rare instances in which patients exhibit extreme incoherence. More commonly, it is the connection between sentences, rather than within sentences, that loses cohesiveness (**Figure 1**).

Behavioral Studies

Direct tests of language production allow researchers to delineate specific components of language that are disrupted. Thought-disordered speech, therefore, may be examined at the level of discourse, semantics, syntax, or phonology. The following sections discuss linguistic impairments at each of these levels in turn.

Discourse

When a patient with thought disorder speaks continuously and without interruption, he or she fails to maintain a sense of semantic cohesiveness throughout the conversation. Researchers have examined this phenomenon by quantifying errors and anomalies during uninterrupted speech. In some of the earliest systematic studies of discourse in schizophrenia, Rochester and Martin (1979) found that patients made an unusual number of reference errors; i.e.,

Many clinical researchers view such language deficits as a reflection of thought disturbance and, consequently, as a formal thought disorder (FTD). The expression of speech is not impaired, as in aphasia. Rather, a patient's speech is thought to represent an underlying disorganized thought process in which loose associations are woven into the conversation (see Critchley, 1964). The issue of whether language impairment in schizophrenia reflects an underlying disruption in thought processes or is a true disorder of speech is open to debate (see Chaika, 1982). It is nevertheless uncontroversial that linguistic disturbances in schizophrenic speech follow a general pattern of anomalies that are related to the presence of FTD. Therefore, this article discusses linguistic processing deficits in schizophrenia within the context of thought disorder.

Formal thought disorder is divided into positive and negative types. Positive FTD is associated with speech that is fluent and detailed; however, communication of ideas is poor. In contrast, negative FTD reflects an impoverished thought process in which speech is nonfluent or barren of content. The primary symptoms of FTD have been defined by Andreasen (1979) and are outlined in Table 1. This classification system has become a standard tool for characterizing language deficits in many psychiatric disorders.

Clinical Observations

Clinicians identify language deficits in schizophrenia through verbal communication with the patient. When FTD is present, the listener may find the dialogue hard to follow. Sometimes the direction of a patient's conversation dissolves as ideas become obliquely related. For example, a patient may start speaking on a particular topic but quickly digress to an irrelevant topic. Alternatively, a patient may answer a question at length in a seemingly normal manner, yet the response itself provides little substantive information. An interesting feature of disorganized speech, however, is that the syntactic and grammatical components of language remain intact, with the exception of relatively rare instances in which patients exhibit extreme incoherence. More commonly, it is the connection between sentences, rather than within sentences, that loses cohesiveness (Figure 1).

Behavioral Studies

Direct tests of language production allow researchers to delineate specific components of language that are disrupted. Thought-disordered speech, therefore, may be examined at the level of discourse, semantics, syntax, or phonology. The following sections discuss linguistic impairments at each of these levels in turn.

Discourse

When a patient with thought disorder speaks continuously and without interruption, he or she fails to maintain a sense of semantic cohesiveness throughout the conversation. Researchers have examined this phenomenon by quantifying errors and anomalies during uninterrupted speech. In some of the earliest systematic studies of discourse in schizophrenia, Rochester and Martin (1979) found that patients made an unusual number of reference errors; i.e.,

Table 1 Primary symptoms of positive and negative formal thought disorder (FTD)

Speech impairment	*Definition*
Positive type	
Derailment	Responses that initially pertain to the topic at hand but gradually slide off track onto another topic that is unrelated
Tangentiality	Responses that are irrelevant and unrelated to the question
Circumstantiality	Long-winded speech that includes extraneous detail, although a logical conclusion is reached eventually
Distractible speech	Repeated and abrupt change of topic during speech in response to a nearby stimulus
Illogicality	Reasoning that is not based on logic or a clear rationale
Stilted speech	Excessively formal speech that may seem pretentious, outdated, or exceedingly proper
Pressure of speech	Rapid and spontaneous speech that may be difficult to interrupt, emphatic, and occur in the absence of prompting by social stimuli
Incoherence	Incomprehensible speech; sentences and word phrases may be lacking syntax, grammar, or semantic connectedness
Clanging	Word choice that is influenced by word sounds rather than semantic relations
Neologisms	Formation of novel words
Word approximations	Unconventional use of words; their new meaning may be understood within the context of conversation but seem peculiar
Negative type	
Poverty of speech	Restricted **amount** of speech; answers to questions contain the least number of words necessary to convey a message; responses are brief, concrete, and often monosyllabic
Poverty of content of speech	Restricted amount of information in speech; answers to questions may be adequate in length, but little substantive information is conveyed
Loss of goal	Failure to reach a conclusion; this behavior may coincide with derailment
Perseveration	Persistent return to words, phrases, or ideas throughout conversation
Echolalia	Repetition of words or phrases recently spoken by another; usually the repetitions reflect the concluding words of another's sentence or question (i.e., an 'echo')
Blocking	Interruption in speech that results from a loss of one's train of thought

Figure 1 An example of extreme disorganized thought in which clipped ideas are merged to form seemingly random phrases. Photograph by Cherie Marvel.

they often failed to connect ideas to previously presented information. They also noted that schizophrenia patients produced longer pauses between sentence clauses and that these lengthy pauses were likely to be followed by a shift in topic.

It has been proposed that speech perception, in addition to speech production, is sometimes impaired in schizophrenia. According to patient accounts gathered by Lawson *et al.*, the problem stems not from an inability to perceive individual words, but from difficulties in tying several words together into a meaningful relationship. For example, one patient explained:

> I can concentrate quite well in what people are saying if they talk simply. It's when they go on into long sentences that I lose the meanings. It just becomes a lot of words that I would need to string together to make sense. (1964: 375)

Semantics

Studies have suggested that difficulties in speech processing in schizophrenia are related to an inability to understand how words are used in context. For example, when tested on pragmatic violations of noun–verb relationships (e.g., *buried* the guitar), thought-disordered patients had difficulty recognizing the implausible noun–verb context (see Kuperberg *et al.*, 2000). Semantic processing deficits have also been demonstrated during tests of confrontation naming (see Barr *et al.*, 1989). When asked to name an object portrayed in a picture, patients with FTD responded with words that were semantically related to the object but nevertheless were incorrect (e.g., saying *microscope* in response to a drawing of a telescope).

Certain tests of semantic knowledge (e.g., priming) are based on a model of spreading semantic associative networks in the brain that become activated during the course of lexical processing. That is, when brain areas become responsive to features of a word, additional brain areas associated with that word are primed for activation. According to Spitzer (1997), FTD patients have an accelerated rate of spreading semantic activation, and this activation extends to nearby indirect association 'nodes' in the brain. This hyperactivation of word associates may lead to loose associations, to thought intrusions, and, ultimately, to obliquely related utterances in speech.

Syntax

There is moderate agreement in the literature that syntax is preserved in schizophrenia. Some instances of syntax errors, however, have been noted during free discourse in schizophrenia patients with severe FTD. 'Word salad' is a term used to describe a pattern of speech that lacks grammar and syntax to the point of incoherence. In a less severe condition, patients may simply omit conjunctions or articles ('and' or 'the') from sentences.

Phonology

Language processing ultimately relies on a fundamental ability to detect the most basic aspects of speech sounds, or phonemes. The detection of phonemes allows a listener to integrate sounds into meaningful words. Kasai *et al.* (2002) used electrophysiological recordings of brain waves in order to record how the brain responds when hearing a sequence of phonemes. Compared to the behavioral responses from controls, patients showed a reduction in the magnitude of electrophysiological responses to changes in phoneme sequences, suggesting that language processing deficits in schizophrenia may begin with a fundamental inability to analyze individual speech sounds. Moreover, patients have consistently shown deficits on cognitive tests that rely on word sounds, such as verbal letter fluency (see Goldberg *et al.*, 1993).

Phonological processing deficits also can be observed in perseveration of phonemes, a term known clinically as 'clanging.' As described by Andreasen (1979), clanging represents a pattern of speech in which the choice of words is governed by sounds rather than semantics. For example, during a test of object naming, a patient who saw a picture of an octopus subsequently responded to a picture of a cactus with *octatoos* and then *captus* (see Barr *et al.*, 1989). Sometimes clanging occurs in the form of rhyming words. Alternatively, there may be a play on homonyms that results in a new direction of conversation: "I'm not making sense [cents] anymore. I have to make dollars" (Andreasen, 1979: 1320).

Neuropathology of Language Deficits

Structural Brain Imaging

A recent review of magnetic resonance imaging findings in schizophrenia found consistent reports of reduced volume in the left superior temporal gyrus (STG), a region important for language and communication (see Shenton *et al.*, 2001). Moreover, smaller left STG volume for patients was inversely correlated with severity of thought disorder. In a majority of the healthy population, the volume of a specific area of the brain that surrounds the posterior STG, known as the planum temporale (PT), is greater on the left than the right side of the brain. This hemispheric asymmetry is **reversed** in schizophrenia, such that patients tend to have larger PT volume on the right side of the brain instead of the left (see Shenton *et al.*, 1992, 2001).

Functional Brain Imaging

Functional brain imaging has produced results that are consistent with the morphometric findings described above. Increased blood flow during language processing is normally higher in the left STG than in the right STG. For patients, however, brain activations show the opposite pattern: greater blood flow is found in the right STG (see Kircher *et al.*, 2002). In addition, the patients' increased activation in the right STG has been correlated with the severity of positive thought disorder.

Less consistent findings have been reported regarding the frontal lobe. Healthy subjects generally show increased activation in the left frontal lobe during tests of word generation. Yet some studies in schizophrenia have reported reduced frontal lobe activation during verbal fluency (see Yurgelun-Todd *et al.*, 1996), whereas other studies have reported no patient activation deficits in this brain region (see Frith *et al.*, 1995).

Cerebellar structural and functional abnormalities in schizophrenia have led to the hypothesis that the cerebellum represents one node within a disrupted fronto-cerebellar system that underlies a variety of cognitive deficits, including language (see Marvel *et al.*, 2004). Neuroimaging studies have reported that increased volume (see Levitt *et al.*, 1999) and blood flow (see Kircher *et al.*, 2001) of the cerebellar vermis, as with the right STG, correlate to a greater severity in symptoms of positive thought disorder.

Summary

Patients with schizophrenia show a variety of linguistic processing deficits that become evident during verbal and written language production. Researchers and clinicians have examined impairments behaviorally at the level of discourse, semantics, syntax, and phonology. A dysfunction at the very early stage of phonological processing may contribute to disruption at higher-order levels of language. Recent advances in neuroimaging have provided new insight into the neural underpinnings of impaired linguistic processing in schizophrenia. Most notably, patients demonstrate a reversal of lateralized asymmetry in which the STG on the right side of the brain tends to be larger and more active than that on the left, a phenomenon that is opposite from what has been found in the healthy population. A disruption in functional circuits that include the frontal lobe and cerebellum also has been implicated.

include Armenian among those belonging to the Indo–European language family, but in view of the material he had at his disposal, he made a great number of important observations that were borne out by subsequent generations of historical linguists. Schlegel undoubtedly deserves a place among the 'founding fathers' of comparative Indo–European grammar, and not only as an interesting 'philological instigator' (see Klin, 1967).

Schlegel, August Wilhelm [from 1815:] von, writer, literary critic, translator, philologist, and student of the Sanskrit language and its literature, elder brother of Friedrich Schlegel (*see* **Schlegel, Friedrich von (1772–1829)**, was born in Hanover (Germany) on September 5, 1767. He studied theology and philosophy at the University of Göttingen, where he was mainly influenced by the philologist C. G. Heyne and the poet G. A. Bürger. Between 1791 and 1795 he was a tutor in Amsterdam. From 1798 he was associate professor at the University of Jena. He moved to Berlin, where he delivered courses of private lectures on literary history (1801–1804). From 1804 till her death in 1817 he was secretary, traveling companion, and literary adviser to Madame de Staël (Anne Louise Germaine de Staël-Holstein, 1766–1817). In 1818 he was appointed professor of the history of art and literature at the University of Bonn, where he established Indic studies, thus becoming the founder of Indic philology in Germany. He died in Bonn on May 12, 1845.

Schlegel was a prominent member of the Romantic movement in Germany and succeeded in transforming the genuine romantic interest in foreign cultures, languages, and literatures, into a systematic scientific approach. He produced excellent translations of Italian and Spanish authors and of the dramas of Shakespeare (in a project later continued by L. Tieck and Tieck's daughter Dorothea). His most influential contributions to the study of language lay in the fields of language typology and reflections on method. As early as 1798 he pointed out the difference between analytical and synthetic languages (Schlegel, 1798: 60 ff.; cf. Schlegel, 1818: 16). By coining the term

'*vergleichende Grammatik*' (Schlegel, 1803: 203) he paved the way for the linguistic theories of his brother Friedrich (e.g., Schlegel, 1808: 28) and significantly contributed to the theoretical evolution of comparative linguistics. He took up and refined Friedrich's theory of language classification (outlined in Schlegel, 1808: 44 ff. and elsewhere) by proposing three types of languages: those without any grammatical structure, languages using affixes, and inflectional languages (Schlegel, 1818: 14 ff.). This theory was much discussed throughout the 19th century. With his severe criticism of J. Grimm's early etymologies (Schlegel, 1815) he gave a decisive impulse to strict methodological rigor in the study of the history of the Germanic languages. He also set the standards for the study of the Sanskrit language by applying the methods of classical philology to the analysis of its literature and the publication of Sanskrit texts (e.g., in his editions of the Bhagavad-Gītā, 1823 and parts of the Rāmāyaṇa, 1829–1838).

Schleicher (see **Figure 1**), an Indo–Europeanist and Slavist, was born on February 19, 1821 in Meiningen, Germany, and died on December 6, 1868 in Jena. He

Figure 1 August Schleicher.

enrolled in the fall of 1840 at the University of Leipzig to study theology, but moved in the spring of 1841 to Tübingen to study theology, philosophy, and Semitic languages with Heinrich Ewald. He abandoned theology two years later to enroll at the University of Bonn, where he studied, among other things, classics with Friedrich Ritschl, oriental languages with Christian Lassen, and German dialects with Friedrich Diez (*see* **Diez, Friedrich (1794–1876)**). He completed his studies with a dissertation on Latin syntax, an examination for high school teaching, and a *venia legendi* for 'Indic language and literature and comparative grammar,' all between January and March 1846. From summer 1846 to early 1848 he taught at Bonn as a *Privatdozent*, adding Slavic to his research interests. He involved himself in the revolutionary movements of 1848–1849, acting as a journalist in various European capitals, especially in Prague, where he learned Czech from a young native, Alois Vaniček, who later became one of his students. He returned to Bonn late in 1849, where his continued work on Slavic languages led, in March 1850, to the offer of an extraordinary professorship, first for classical philology, subsequently for comparative linguistics and Sanskrit, at the University of Prague, where, in 1853 he became a full professor, with German linguistics added to his subjects. There Georg Curtius (*see*

Schlegel was born in Hanover on March 10, 1772, and died in Dresden on January 12, 1829. In the annals of linguistic science he is usually accorded only a minor role. His strong involvement in the Romantic movement and his literary production may explain why he is usually seen as a poet and literary critic, and hardly ever as a linguist. It is true that his interest in Oriental studies had originally been aroused by translations from Sanskrit and Persian literature. The book he wrote during 1805 and 1807 and for which he became famous, *Ueber die Sprache und Weisheit der Indier*, contains chapters of approximately equal length on the philosophy and theology (Schlegel, 1808: 89–153) and on the '*historische Ideen*' concerning India (ibid. 157–230), with translations of Indian poetry into German (ibid. 231–324). Yet there is no doubt that the first part on language ('*Von der Sprache*,' 1–86) attracted the most enduring interest among his contemporaries. The fact that the King of Bavaria granted two of his subjects, Othmar Frank and Franz Bopp (*see* **Bopp, Franz (1791–1867)**), scholarships to pursue the study of Persian and Sanskrit in Paris a few years later may serve as an indication of the importance that was soon attached to Oriental studies, and this largely as a result of Schlegel's book. His importance in the history of linguistic science rests on this one work; it appears, however, that once the year 1816, the date of Bopp's *Conjugationssystem*, had been chosen by historians as marking the beginning of linguistics, Schlegel's book was only mentioned as precursory. It was no longer read, although the so-called founding fathers of comparative–historical philology, Bopp (*see* **Bopp, Franz (1791–1867)**), Rask (see *Rask*, *Rasmus Kristian*), and Grimm (*see* **Grimm, Jacob Ludwig Carl (1785–1863)**), acknowledged their indebtedness to his work. Schlegel is traditionally credited with the first use of the term '*vergleichende Grammatik*.' However, others, like J. S. Vater, had used it in 1801, and the elder Schlegel, August Wilhelm (*see* **Schlegel, August Wilhelm von (1767–1845)**), used it in 1803 before his brother. But it is clear from Friedrich Schlegel's book (p. 28) that he had been inspired by the example of Blumenbach and Cuvier's Comparative Anatomy. By today's standards, Schlegel had a checkered career; following the study of law in Göttingen and Leipzig, he soon turned to literature as his main occupation, circulating among the Romantics as well as the people at the Court of Weimar, notably Goethe, Schiller, and Herder (*see* **Herder, Johann Gottfried (1744–1803)**), who was largely responsible for creating the general climate of the time that expected new and profound ideas to come from the East ('*ex Oriente lux*'). Schlegel's exposure to the writings of Sir William Jones (*see* **Jones, William, Sir (1746–1794)**) led him to travel to Paris, where Persian, Arabic, and other Oriental languages were taught. He was introduced to Persian by Antoine Léonard de Chézy soon after his arrival in 1802, and familiarized himself with the ancient language of India through Alexander Hamilton, from whom he took private lessons during 1803 and 1804. He copied Sanskrit manuscripts and translated literary texts; for a living, he gave lectures on German literature and philosophy.

Ueber die Sprache und Weisheit der Indier was important for the development of comparative–historical as well as typological linguistics in the 19th century. Schlegel's suggestion to compare grammatical features in order to establish genetic relationships, though not entirely new, was influential. For instance, his suggestion to investigate the conjugation system of Sanskrit in comparison with all the languages thought to be related to it led Bopp to his first work; his evolutionary view of language paved the way for Grimm's emphasis on the historical treatment of language, and his classification of languages according to morphological structure initiated an entire research program. This went from Wilhelm von Humboldt (*see* **Humboldt, Wilhelm von (1767–1835)**) to Steinthal (*see* **Steinthal, Heymann (1823–1899)**) to Sapir (see *Sapir*, *Edward*), to Greenberg (*see* **Greenberg, Joseph H. (1915–2001)**), and beyond, especially after his brother August had introduced the synthetic/analytic distinction in his 1818 essay on the history of the Romance languages. Timpanaro (1972: 77) pointed out that when Schlegel discussed at length questions of change and language mixture, he anticipated substratum theory, usually associated with Ascoli (*see* **Ascoli, Graziadio Isaia (1829–1907)**), Schuchardt (*see* **Schuchardt, Hugo (1842–1927)**), and others at the end of the 19th century. Schlegel maintained that language contact and the resulting borrowings made it difficult at times to identify all 'Sanskritic' languages, making it necessary to consider what we may call the external history of a given language, in addition to submitting it to close morphological analysis. In discussing linguistic contamination and the question of language descent, Schlegel drew particular attention to Armenian, in which he found many similarities with Latin, Greek, Persian, and German roots, and to agreements in grammatical structure. He was not quite ready to

include Armenian among those belonging to the Indo–European language family, but in view of the material he had at his disposal, he made a great number of important observations that were borne out by subsequent generations of historical linguists. Schlegel undoubtedly deserves a place among the 'founding fathers' of comparative Indo–European grammar, and not only as an interesting 'philological instigator' (see Klin, 1967).

Schleicher (see Figure 1), an Indo–Europeanist and Slavist, was born on February 19, 1821 in Meiningen, Germany, and died on December 6, 1868 in Jena. He

Figure 1 August Schleicher.

enrolled in the fall of 1840 at the University of Leipzig to study theology, but moved in the spring of 1841 to Tübingen to study theology, philosophy, and Semitic languages with Heinrich Ewald. He abandoned theology two years later to enroll at the University of Bonn, where he studied, among other things, classics with Friedrich Ritschl, oriental languages with Christian Lassen, and German dialects with Friedrich Diez (*see* **Diez, Friedrich (1794–1876)**). He completed his studies with a dissertation on Latin syntax, an examination for high school teaching, and a *venia legendi* for 'Indic language and literature and comparative grammar,' all between January and March 1846. From summer 1846 to early 1848 he taught at Bonn as a *Privatdozent*, adding Slavic to his research interests. He involved himself in the revolutionary movements of 1848–1849, acting as a journalist in various European capitals, especially in Prague, where he learned Czech from a young native, Alois Vaniček, who later became one of his students. He returned to Bonn late in 1849, where his continued work on Slavic languages led, in March 1850, to the offer of an extraordinary professorship, first for classical philology, subsequently for comparative linguistics and Sanskrit, at the University of Prague, where, in 1853 he became a full professor, with German linguistics added to his subjects. There Georg Curtius (*see*

Curtius, Georg (1820–1885)) was his colleague. In 1857, after difficult years (Schleicher, a foreigner, a Protestant, and a man of integrity and honesty engaged in matters concerning political freedom and justice, was subjected to various indignities at the hand of the Austrian authorities and misguided Czech nationalists), he was glad to accept a lesser position at the University in Jena, where he remained as an *ordentlicher Honorarprofessor* for comparative linguistics and German philology, despite offers from Warsaw and the Academy of St Petersburg (both in 1862) and Dorpat (in 1863), until his premature death at the age of 47 years.

Contrary to widespread belief, Schleicher's views on language and linguistics were fixed early in his career. Shortly after the publication of his first book, *Zur vergleichenden Sprachengeschichte* (1848), Schleicher worked out a naturalistic conception of language and a research program inspired by Hegelian philosophy and the exact analytical methods of the natural sciences, in particular, botany and geology. His second book (Schleicher, 1850) documents this turn to a natural science conception of linguistics very well. In his *Die Deutsche Sprache* (1860) and several other subsequent publications, he repeated almost verbatim what he had first pronounced in the 1850 book. Significantly, he published his first *Stammbäume* (genealogical trees) in 1853, six years before the publication of Darwin's *Origin of Species*, and in 1859 he introduced the term '*Morphologie*' into linguistic nomenclature.

Schleicher was the most distinguished Indo–Europeanist of his generation and an accomplished synthesizer of the accumulated linguistic knowledge of his time, as may be gathered from the various editions of his *Compendium* (1861–1862). Although he was not the first to use the asterisk, it was he who developed the method of reconstruction in comparative linguistics on which subsequent generations built. His famous story written in Indo–European was not 'a joke' (as Delbrück held in 1880; *see also* **Delbrück, Berthold (1842–1922)**) but a demonstration of the comparative method. In the fields of Baltic and Slavic as well as dialectology and the study of child language (1861) he was innovative; his synthesis of Indo–European phonology and morphology in the *Compendium* served as a model for subsequent research, especially Brugmann and Delbrück's *Grundriss* (1886–1916). Schleicher is nowadays best known for his Darwinian essays (e.g., 1863), although these are in fact his weakest works. His most distinguished students were Jan Baudouin de Courtenay, August Leskien (*see* **Leskien, August (1840–1916)**), Johannes Schmidt (*see* **Schmidt, Johannes (1843–1901)**), and Hugo Schuchardt (**Schuchardt, Hugo (1842–1927)**).

Schlieben-Lange, Brigitte (1943–2000)

P Swiggers, Katholieke Universiteit Leuven, Leuven, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Brigitte Schlieben-Lange, who died on September 14, 2000, after a short period of serious illness, was one of the first women to obtain a chair of Romance Philology in the German-speaking academic world (1974, at Frankfurt University). She studied Romance and Germanic philology, general linguistics, and philosophy in Munich, Aix-en-Provence, Marseille, and Tübingen. She felt especially attracted by Eugenio Coseriu's general linguistics, with its focus on Romance materials. In 1970 she received her Ph.D. in Tübingen, under the supervision of Coseriu. Early on in her career she focused on the languages that mark the transition between Gallo–Romance and Ibero-Romance, viz. Occitan and Catalan (1971a, 1971b); in her subsequent academic teaching and research (from 1974 to 1991 in Frankfurt, from 1991 on in Tübingen) she most often worked on the national languages French, Spanish, and Italian, while in the late 1990s she devoted her efforts to the study of Brazilian Portuguese.

Schlieben-Lange's interests were hardly in descriptive grammar and lexicology; her focus was – through a fruitful integration of linguistic theory, the study of literature and culture, and text-oriented language history – on sociolinguistic aspects. She was especially interested in language standardization, codification, and revitalization, in problems of intrasocietal and intercultural communication, in the relationship between oral and written culture, and in the history of 'traditions of speaking,' a concept which she developed (1983) and which shows much more affinity to continental discourse analysis (from a sociological point of view) than to Anglo–American ethnography of speaking. She wrote textbooks on sociolinguistics and pragmatics (1973, 1975), which have become standard references in the German-speaking world. The overall frame for her sociolinguistic and pragmatic studies was language history, viewed as the complex reconstructed history of language planning and development, descriptive linguistic work, linguistic theorizing, and traditions of speaking and writing.

Brigitte Schlieben-Lange was well at home in the study of the early periods of Romance languages and language study, but her favorite period was the turn from the 18th to the 19th century. She was a specialist of the lexicographical production during the French revolutionary period (1981, 2000) and of the diffusion of the linguistic and philosophical ideas of the French *idéologues* (a topic on which she directed a wide-spanning research project, 1989–1994). She not only contributed important insights to Romance sociolinguistics and language history and to the study of orality and 'scriptural culture and codification' (*Schriftlichkeit*; *Verschriftung*), but she also played an important role in the academic emancipation of female linguists, was co-editor of two journals (*Zeitschrift für Literaturwissenschaft und Linguistik*; *Zeitschrift für Katalanistik*), and was editor of important collective volumes on writing processes (1987, 1997), textual culture (1995), and (linguistic) alterity (1998).

Schmeller, Johann Andreas (1785–1852)

W H Veith, University of Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Johann Andreas Schmeller was born in Tirschenreuth, north Bavaria, close to the Czech border, but grew up in a small village north of Munich. At his grammar school in Munich, he became familiar with the ideas of the Enlightenment (Leibniz) and of the Swiss educational reformer Pestalozzi. Since he could not afford university studies and Schmeller failed to find a publisher for his first booklet of 1803 (Schmeller, 1803), he walked to Switzerland hoping that Pestalozzi could help him and would appoint him as a teacher. This failed, and he joined the Swiss military in Spanish services. Performing Pestalozzi's principles, he taught languages at military schools in Tarragona and Madrid, and, finally, at a private teaching institute in Basle (1806–1813). In 1814, he joined a Bavarian military brigade at the rank of a first lieutenant. In 1816, the Bavarian Academy of Science asked him to make a Bavarian dialect dictionary. He had already seen parts of Franz Joseph Stalder's Swiss dialect dictionary by 1806 (Stalder, 1806–1812), from which he drew inspiration. He also had consulted a copy of Stalder's dictionary, Leonz Füglistaller, in St. Gallen (cf. Brunner, 1997: 13).

As a consequence of his Bavarian dialect grammar (1821), he was appointed member of the Academy in 1823; in 1827, he was honored with a doctoral degree, and in 1828, he received the title of an extraordinary professor for Old German Literature and Language at Munich university. As curator of the Royal Court and State Library (1829), he finally was free of all financial worries; he quit military and private teaching. His new activity was to systematize about 25 000 handwritten documents confiscated when 150 monasteries were secularized in 1803, but he also continued publishing. His career culminated when he was appointment full professor in 1846. Schmeller died of cholera in 1852.

As an introduction to the Bavarian dialect dictionary, Schmeller had planned a chapter on phonetics. But this was extended to a complete grammar, published in 1821. In accordance with the ideas set out in writing in 1803 (Schmeller, 1803), Schmeller invented his own phonetic alphabet. To a certain extent influenced by Jacob Grimm's *Deutsche Grammatik* [German grammar] (1st ed. 1819), Schmeller changed his early conception dating from 1818 (Naumann, 1988: 84). His method of description was both synchronic-comparative (*dialect–dialect*/'*Standard*'), and somewhat historical-comparative. Both grammar and dictionary comprised non-Bavarian dialects within the Bavarian kingdom.

Schmeller used three types of information: (a) written documents, (b) spoken language won through a network of informants of whom each was responsible for a certain area—a method that was worthy of imitation, and (c) his own explorations. (For the influence of Leibniz, see Wolf, 1988: 37; for the arrangement of the dictionary, *see* **Dialects: Early European Studies**).

Schmeller was very versatile: 70 printed and 22 unprinted publications were listed by Brunner (1997). The most important ones were the *Bavarian dialect grammar* (1821), the *Bavarian dialect dictionary* (4 vols. 1827–1837), the grammar and, posthumous 1855, the dictionary of the 'Cimbri' (Schmeller, 1984) (i.e., of Bavarian dialects near Vicenza/Verona, Italy). This way, Schmeller was the founder of German dialectology and of onomastics, mostly integrated in the Bavarian dialect dictionary (see Bauer, 1985). Next to the Grimm brothers and Karl Lachmann, Schmeller was a famous editor of medieval texts, e.g., of *Heliand* 1830, *Muspilli* 1832, *Tatian* 1841, *Carmina Burana* 1847. Finally, he was one of the founders of Albanology and of Czech linguistics. To place Schmeller in the history of ideas, see Harnisch (2002).

Schmidt, Johannes (1843–1901)

J van Pottelberge, Ghent University, Ghent, Belgium

© 2006 Elsevier Ltd. All rights reserved.

Johannes Schmidt was one of the most prominent Indo-Europeanists of his era. Born on July 29, 1843 in Prenzlau (Prussia, northeastern Germany), he was orphaned at the age of eight and subsequently moved to the home of his uncle, the classical philologist and grammar school teacher K. E. A. Schmidt, in Stettin (now Szczecin, Poland). From 1860 he studied classical philology in Bonn under Friedrich Ritschl and from 1862 Indo-European languages in Jena under August Schleicher. In 1865 he obtained his doctoral degree in Jena, and in 1868 his *Habilitation* in Bonn, where he received a full professorship in 1873. The same year he was appointed to Graz (Austria), and in 1876 he received the prestigious Chair of Comparative Linguistics in Berlin, which until 1867 had been held by Franz Bopp. Schmidt stayed in Berlin until his death on July 4, 1901, after a lingering illness of several years. Paul Kretschmer, Wilhelm Meyer-Lübke, and Holger Pedersen are the most famous among his many pupils.

Schmidt was averse to all schematization, being instead a meticulous, data-oriented comparativist. His work (which displays a distinct interest in Slavic, Germanic, and most of all Greek) consisted exclusively of studies into comparative Indo-European phonology and morphology. Major achievements to which Schmidt contributed include the Law of the Palatals in Indo-Aryan and proof that the original Indo-European vocalism distinguished three non-high vowels (*a*, *e*, *o*), as essentially mirrored by the European languages (and not by Sanskrit, which had only *a*). His reluctance to draw correlations and to engage in theoretical issues renders most of his work outdated, however.

A notable exception is *Die verwantschaftsverhältnisse der indogermanischen sprachen* (1872). Here Schmidt argued against Schleicher's genealogical tree and the concept of intermediary parent languages (e.g., Greco-Italic or European), which had been generally accepted until then. He held that the Indo-European language families must have formed a kind of geographical continuum of 'waves' from Asia to Europe in which each family was more closely related to its neighbors on either side, much like dialect areas. The interpretation of the wave as an image for a linguistic innovation radiating from a focal point (the so-called 'wave theory' in dialectology) is, however, of later date, and its attribution to Schmidt, though common, is erroneous.

From 1880 until his death, Schmidt was editor of the renowned *Zeitschrift für vergleichende Sprachforschung* ("Kuhn's Zeitschrift"), in which most of his major articles appeared. The Neogrammarians acknowledged Schmidt's erudition and would have liked him to take their side, but their self-proclaimed vanguardism clashed with Schmidt's own self-consciousness and conservative temper. The latter is revealed by several polemical exchanges between them, e.g., concerning the Neogrammarian principle of exceptionless sound laws, which Schmidt credited to Schleicher.

Schmidt-Wiegand, Ruth (b. 1926)

S Kürschner, Institut für Vergleichende Germanische Philologie und Skandinavistik, Freiburg im Breisgau, Germany

© 2006 Elsevier Ltd. All rights reserved.

Ruth Schmidt-Wiegand was born on January 1, 1926 in Berlin. Her scientific career began with university studies in German, history, philosophy, and theology in 1946. In 1951 she attained the doctoral grade from the University of Greifswald with a thesis on the origin of the 'Lex Salica.' The language of law would become Schmidt-Wiegand's main research topic in the combination of linguistics and the study of law: she established a link between law texts and the description of laws in literature throughout the development of the German language. After a research period at Bonn, Schmidt-Wiegand's postdoctoral thesis (Münster, 1970) focused on the historical development of legal word geography. The law texts from the German Middle Ages became Schmidt-Wiegand's main interest. In parallel, she documented main steps in the establishment of the German early written language. In 1971 she became professor of German linguistics in Münster and worked in a special research group on the Middle Ages from 1972.

Schmidt-Wiegand started to work in a second special research group on pragmatical writing in the Middle Ages in 1982. She became project manager of the subgroup on 'law books as media expressing pragmatical writing.' In this period, she was responsible for the edition of picture manuscripts of the law text *Sachsenspiegel*, which marks the beginning of written medieval German law texts. The edition made the Wolfenbüttel (1993) and the Oldenburg (1995) manuscripts available to a greater public for the first time. In her scientific contributions to the commentary supplements, and in other contributions dealing with these picture manuscripts, Schmidt-Wiegand broke the boundaries of linguistics in another way, by integrating the manuscripts' pictures into the linguistic perspective.

In her main research topic, the study of historical law language, Schmidt-Wiegand was one of the editors of the *Handbook of the history of the German law* and is part of the editing team of three German periodicals and a book series. She edited about 15 books on the history of law and legal language, mostly interdisciplinary, and wrote 6 monographs. She contributed to the research on the 19th-century German grammarians Grimm, among other things, by a new edition of Jacob Grimm's old law text collection *Weisthümer*. In addition, Schmidt-Wiegand's scientific work consists of more than 110 papers, numerous dictionary and lexicon articles, and book reviews on language history, and on the language and science of law. All of these up to the year of 1996 can be found in publication lists in the Festschrifts Schmidt-Wiegand (1991) and Höfinghoff *et al.* (1996), which appeared after a first Festschrift from 1986. Schmidt-Wiegand was honored with several awards and attained an honorary doctorate from the University of Marburg in 1985.

Schottelius, Justus Georg (1612–1676)

K R Jankowsky, Georgetown University, Washington, DC, USA

© 2006 Elsevier Ltd. All rights reserved.

Justus Georg Schottelius (Figure 1) was born in 1612 in Einbeck, in southern Lower Saxony, Germany, and died in 1676 in Wolfenbüttel. Although he originally planned to train for a craftsman's career, he managed to obtain the qualifications for university studies, which he began in Leyden (1633–1636), subsequently moving to Wittenberg. With a *disputatio* in Helmstedt, he earned a Dr. jur. degree in 1643.

His membership a year earlier in the *Fruchtbringende Gesellschaft* (fruitful society), founded in 1617 with the aim of cultivating the German language, strengthened his belief in the crucial need to become actively involved in protecting the German language from overbearing foreign influences. His initial publication, *Lamentatio Germaniae expirantis* (1640), is an inspiring 'battle cry' as well as an outline of the agenda for a determined action plan on which he focused for the rest of his life.

Schottelius's (1663) first programmatic item was to write a comprehensive grammar of the German language. It turned out to be the first complete descriptive grammar of German. An early reviewer (Jagemann, 1893: 410) admiringly called him the "Jacob Grimm of the 17th century," which is hardly an exaggeration, even if this accolade is restricted to considering the few predecessors Schottelius could rely on, compared to the numerous predecessors whose work was available to Grimm.

Figure 1 Schottelius, Justus Georg (1612–1676).

Schottelius acquired all there was to know about the scientific study of language in his time. No languages other than the 'holy three,' Latin, Greek, and Hebrew, were deemed objects worthy of scientific investigation. While his few predecessors were still largely dependent upon the Latin model in their grammatical writings, Schottelius succeeded in breaking new ground in several respects.

Claiming that German was older than both Latin and Greek, and that in importance and age it was second only to Hebrew, Schottelius made the case that placing a much greater emphasis on the 'the people's language' was long overdue. He appealed to the patriotism of his German compatriots and pointed to France and Italy as countries much more successful than Germany in achieving a status of notability for their respective languages. For him, language went far beyond being a mere instrument of communication: "What we do and what we do not do is preserved with us, kept, and handed on through the German language. Through it we approach God and enter heaven; we might even say that through it we keep body and soul together" (1641: Introduction). He was fully aware that the existing German languages were only dialects, and since in his opinion all dialects are flawed and hence cannot serve as substitute for a German *HauptSprache,* or common standard language, he set out to define what that thus-far elusive national language should be like, hoping in this way to facilitate its birth and continued growth: "*Die Hochteutsche Sprache … ist nicht ein Dialectus eigentlich/sondern lingua ipsa Germanica, sicut viri docti, sapientes & periti eam tandem receperunt & usurpant*" (The High German Language … is not actually a dialect but the German language itself such as wise and experienced scholars at long last have retained it and are using it) (1663: 174).

Schottelius's *Ausführliche Arbeit* (1663), at 1529 pages, is his meritorious *opus magnum*. Paul Hankamer (1927: 124) conferred on it the title *Summa philologica*, and Wolfgang Hecht, in the 1967 reprint of that work, raised its stature even further: "The 'Ausführliche Arbeit' is not only Schottelius' summa philologica, but beyond this also that of the entire era. Nowhere else have the grammatical concepts and

the theoretical-linguistic thoughts of the epoch between Ickelsamer and Leibniz been treated more comprehensively than here" (Epilog, p. 7).

In 10 *Lobreden* (hymns of praise, eulogies), Schottelius praised the "*Uhraltertuhm/Reinlichkeit/Eigenschaft/Vermögen/Unvergleichlichkeit/Grundrichtigkeit*" (antiquity, purity, quality, capability, incomparability, fundamental correctness) of the German language and went on to present its grammar and the rules of word formation and derivation. In a major portion of this work (pp. 1269–1450) he dealt with the "*Stammwörter der Teutschen Sprache*" (roots or stem words of the German language), the (mostly monosyllabic) building blocks of the language, from which all other words are derived. He ascribed to them "superior qualities" such as being of native origin, sounding well, and being able to be sufficiently expanded. He also established their "*Grundrichtigkeit*" by tracing them back to what he believed was their ideal original state. With this inclusion of the historical dimension, he moved closer to a true understanding of the developmental aspect of language history.

Schottelius's list contains approximately 5000 stem word entries. According to his plan they were to form the nucleus of a comprehensive dictionary of the German language, a project keenly supported by Leibniz, which did, however, not proceed beyond the planning stage.

In the context of Schottelius's attempt to replace foreign words with native equivalents, it is worth mentioning that to this day we use grammatical terms that he created, for instance, *Sprachlehre* (grammar), *Wörterbuch* (dictionary), *Zeitwort* (verb), *Fragezeichen* (question mark), and *Zahlwort* (numeral).

Last but not least, it is important to note Schottelius's emphasis on the artistic dimension of language, requiring the grammarian to discover and make explicit the beauty of language. In addition to stressing this aspect in his *Lobreden*, he incorporated in his *Ausführliche Arbeit* all major portions of his *Teutsche Vers- oder Reimkunst* of 1645, thus illustrating as essential the interrelatedness of the poet's and the grammarian's accomplishments.

Schuchardt, Hugo (1842–1927)

W H Veith, University of Mainz, Mainz, Germany

© 2006 Elsevier Ltd. All rights reserved.

Hugo Schuchardt was born in Gotha (Thuringia, Central Germany) as the son of a German lawyer and a French-speaking mother from Switzerland. He studied in Jena under August Schleicher, the mentor of the Neo-Grammarians, also in Bonn under Friedrich Dietz, the founder of Romance linguistics in Germany, and Friedrich Wilhelm Ritschl, Professor of Classical Philology (Latin), who was also a teacher of Schleicher's and even of Nietzsche's. Schuchardt's doctoral thesis submitted to Bonn university in 1862 became the basis of the famous book on the vocalism of Vulgar Latin (3 vols 1866–1868), building a bridge between Classical and Romance Philology.

In 1870, Schuchardt qualified as a university lecturer (*Dozent*) in Leipzig by submitting a postdoctoral thesis on a sound change of a Romance dialect in Switzerland. In 1873, he became a full professor of Romance Philology in Halle, Central Germany, and thereafter in Graz, Austria (1876–1900).

Schuchardt's fields of activity were immense and diverse, at first without a unified theory, but with individually developed methods. Spitzer (1928) gives a list of 770 publications. His teachers' influence on his first publications was unmistakable, as can be seen by the use of a stemma to describe the "inner history of the Roman vernacular" (Schuchardt, 1866–1868 vol. I: 82), a method used by Ritschl to depict "the descent of manuscripts from a common source," and by Schleicher to establish a family tree of the Indo-Germanic languages. Later, however, Schuchardt turned against Schleicher and the rigid sound laws of the Neo-Grammarians. In his conference on the classification of Romance dialects (1870, printed in 1890; see Spitzer, 1928: 166–188), he argued against Schleicher's transfer of Darwin's genealogical classification to linguistics: the geographical variation of dialects is continuous and rarely abrupt so that a clear-cut dialect classification is rather impossible. An exception is the contrast between city and rural language (see Schuchardt, 1885; Lichem and Simon, 1980). Although frequently ignored, this notion has been accepted from today's point of view.

From 1871 on (Spitzer, 1928), Schuchardt was occupied with etymologies and the cultural background of the words discussed and with descriptions of Portuguese-, French-, Spanish-, English- and Dutch-based creole languages, becoming the founder of creolistics. His research activities shed light on language mixture in Europe, Africa, and Asia (Schuchardt, 1884, 1886, 1906, 1918) involving, for example, Rhaeto-Romance, (Daco-)Romanian, Albanian, French, Slavo-Italian, Slavo-German, Spanish, Portuguese, English, Welsh, Basque, Magyar, Georgian; Berber, Bengali and Melanesian languages. This brought him to a general hypothesis of language change by mixture: "There is no completely unmixed language" ([1883] see Spitzer, 1928: 153). Schuchardt laid the foundations of the modern discipline of Languages in Contact (Weinreich, 1953).

No less famous were his studies on Basque (from 1887; Schuchardt, 1906, 1925a). Further discussed was the origin of languages and the question of an artificial world language, for example, Volapük (Schuchardt, 1894). In Schuchardt (1925b), the discussion of research methods is combined with autobiographical information.

Schuchardt considered his chair as a job, his research as a duty to study the phenomenon of language. His publications may give the impression of a great divergence, if not of oddness, but all in all, they build a mosaic of Schuchardt's linguistic theory after which there is only one linguistics: general linguistics and its application to special language systems. The development of language depends on the speakers, and it has ethnic, social, and psychic ties. The mixture of different cultures leads to the mixture of language systems, as shown in Schuchardt's studies on creole languages and pidgins, and on the lingua franca, a term used by Schuchardt beginning in 1909.

Language development cannot be grasped by the description of sound laws because it is brought about by the change of concepts, thoughts and meaning, thus regulating a change in expression. Concepts are based on the things of the real world, which therefore have to be included in the objectives of linguistic research. Pictures or even an atlas of pictures improve their description, a demand of Schuchardt's with respect to Comenius who, in 1658 already, used pictures for linguistic and educational purposes (Spitzer, 1928, no. 385, 421). Words make the cultural background of things accessible to the researcher. Therefore word history comes before language history and its correlate: the history of culture. It is this *Sachwortkunde* ('science of things and words') on which a new field of linguistic research is grounded and by which Schuchardt finds himself in full agreement with the famous French dialectologist Jules Gilliéron and his methods of etymology. Schuchardt's perspective is contrary to that of Rudolf Meringer (also a professor in Graz) who founded the journal *Wörter und Sachen* ('Words and Things') in 1909. In his article 'Sachen und Wörter' (Spitzer, 1928: 122–135), Schuchardt

stated that things as stable forms of existence are primary and words are secondary. These ideas were realized, later on, in the *AIS* (Linguistic and ethnographic Atlas of Italy and south Switzerland, K Jaberg & J Jud (eds.), vols I–VIII. 1928–1940), and also in the new French regional dialect atlases, so that Schuchardt's idea to collect all expressions referring to given concepts as existing in related dialects was partly realized. Concepts depend indeed on cultures and societies, but, with this restriction, they are quite universal while expressions (words) depend on particular language systems (dialects). "All our languages as dialects of the one, the only one, the human language, that is Schuchardt's vision" (Wandruszka in Lichen and Simon (1980): 312, translated from German).

Schütz, Alfred (1899–1959)

S O'Neill, University of Oklahoma, Norman, OK, USA

© 2006 Elsevier Ltd. All rights reserved.

Alfred Schütz was born in Vienna, Austria, on April 13, 1899. In 1918, he entered the University of Vienna, earning a doctorate in law, and continuing his postgraduate studies in the social sciences until 1923. There Schütz encountered the sociology of Max Weber, whose focus on the meanings ascribed to social action made a lasting impression on him. Yet, Weber's abstract treatment of the individual's reality left Schütz dissatisfied. Later Schütz found renewed inspiration in the phenomenological writings of Edmund Husserl and Bergson, who had developed a sophisticated methodology for studying human consciousness, one that Schütz hoped to graft onto a new sociology.

In 1932, Schütz published his major statement in a work entitled *The phenomenology of social relations*, for which he received praise from Husserl himself. Fleeing the German invasion of his native Austria, Schütz immigrated to the United States in 1939, where he joined the Graduate Faculty of the New School for Social Research in New York City in 1943, first as a lecturer, then as professor of sociology, starting in 1952. In 1956, he was also appointed professor of philosophy. Schütz died in New York on May 20, 1959.

Schütz is best known for his pioneering writings on phenomenological sociology, a discipline that explores relationships between human social action

stated that things as stable forms of existence are primary and words are secondary. Alfred Schütz was born in Vienna, Austria, on April 13, 1899. In 1918, he entered the University of Vienna, earning a doctorate in law, and continuing his postgraduate studies in the social sciences until 1923. There Schütz encountered the sociology of Max Weber, whose focus on the meanings ascribed to social action made a lasting impression on him. Yet, Weber's abstract treatment of the individual's reality left Schütz dissatisfied. Later Schütz found renewed inspiration in the phenomenological writings of Edmund Husserl and Bergson, who had developed a sophisticated methodology for studying human consciousness, one that Schütz hoped to graft onto a new sociology.

In 1932, Schütz published his major statement in a work entitled *The phenomenology of social relations*, for which he received praise from Husserl himself. Fleeing the German invasion of his native Austria, Schütz immigrated to the United States in 1939, where he joined the Graduate Faculty of the New School for Social Research in New York City in 1943, first as a lecturer, then as professor of sociology, starting in 1952. In 1956, he was also appointed professor of philosophy. Schütz died in New York on May 20, 1959.

Schütz is best known for his pioneering writings on phenomenological sociology, a discipline that explores relationships between human social action

and associated states of individual consciousness. For Schütz, language, as system of conventional signs, plays a central role in transmitting the many modes of thought expressed within a society, exerting a profound, though ultimately contestable, influence on personal worldview. Schütz starts with the assumption that speakers differ in their experiences, arguing that the meanings provided in language 'stabilize' individual perception in social encounters, though without leveling out personal differences. Because speakers use language to creative ends, worldview is not static, but socially constructed; though Schütz maintains that languages preserve historically significant systems of thought, which are slow to change. At the same time, knowledge of language is not uniform, for Schütz, but reflects the scope of speakers' social experiences.

For Schütz, language exists at the border zone between the private worlds of individuals, facilitating a temporary exchange between otherwise separate streams of consciousness. Schütz argues that communication rests on the principle of 'appresentation,' or the capacity of signs trigger absent orders of reality in consciousness. Below the threshold of language, even objects are capable of conjuring imagery, a process that Schütz calls an "indication" if the association is a natural one (e.g., smoke for fire) or a 'mark' if deliberate (e.g., a ribbon around the finger as a reminder). So far, these meanings are private. Yet with signs, such as those found in language, the meaning is 'intersubjective,' because an object of perception, such as a sound pattern, triggers similar, though not identical, associations for all parties. Though established on an intersubjective basis, Schütz argues that a meaning eventually becomes 'detached' from its original context, where this meaning is generalized until applied in another encounter, where the sign can take on subtle new shades of meaning.

Schütz continued to revise his phenomenological approach to sociology over his career, writing a series of articles that were later drawn together in his *Collected papers I-III* and presented in his posthumous *The structures of the life world [I–II]*. For many years Schütz served on the editorial board of the journal *Philosophy and Phenomenological Research*.

Scope and Binding: Semantic Aspects

A Szabolcsi, New York University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The scope of an expression E is the domain within which E's interpretation can impact that of other expressions. In the simplest cases this domain coincides with E's sister constituent (E's syntactic scope). The reading where E_1 scopes over some E_2 is notated as $E_1 > E_2$. E_1's impact on E_2 may be of different kinds. Some examples follow. In (1) teachers may vary with boys; similarly in (2) if scope is used to effect pronoun binding. In (3) negation eliminates existential import. In (4) the Grail need not exist in the actual world. In (5) the polarity item is licensed.

(1) Every boy saw a teacher.
'every boy > a teacher'

(2) Every boy saw the teacher who flunked him.
'every boy > him'

(3) Nobody drew a circle.
'nobody > a circle'

(4) Parsifal seeks the Grail.
'seek > the Grail'

(5) You have not responded yet.
'not > yet'

and associated states of individual consciousness. For Schütz, language, as system of conventional signs, plays a central role in transmitting the many modes of thought expressed within a society, exerting a profound, though ultimately contestable, influence on personal worldview. Schütz starts with the assumption that speakers differ in their experiences, arguing that the meanings provided in language 'stabilize' individual perception in social encounters, though without leveling out personal differences. Because speakers use language to creative ends, worldview is not static, but socially constructed; though Schütz maintains that languages preserve historically significant systems of thought, which are slow to change. At the same time, knowledge of language is not uniform, for Schütz, but reflects the scope of speakers' social experiences.

For Schütz, language exists at the border zone between the private worlds of individuals, facilitating a temporary exchange between otherwise separate streams of consciousness. Schütz argues that communication rests on the principle of 'appresentation,' or the capacity of signs trigger absent orders of reality in consciousness. Below the threshold of language, even objects are capable of conjuring imagery, a process that Schütz calls an "indication" if the association is a natural one (e.g., smoke for fire) or a 'mark' if deliberate (e.g., a ribbon around the finger as a reminder). So far, these meanings are private. Yet with signs, such as those found in language, the meaning is 'intersubjective,' because an object of perception, such as a sound pattern, triggers similar, though not identical, associations for all parties. Though established on an intersubjective basis, Schütz argues that a meaning eventually becomes 'detached' from its original context, where this meaning is generalized until applied in another encounter, where the sign can take on subtle new shades of meaning.

Schütz continued to revise his phenomenological approach to sociology over his career, writing a series of articles that were later drawn together in his *Collected papers I-III* and presented in his posthumous *The structures of the life world [I–II]*. For many years Schütz served on the editorial board of the journal *Philosophy and Phenomenological Research*.

Scope and Binding: Semantic Aspects

A Szabolcsi, New York University, New York, NY, USA

© 2006 Elsevier Ltd. All rights reserved.

The scope of an expression E is the domain within which E's interpretation can impact that of other expressions. In the simplest cases this domain coincides with E's sister constituent (E's syntactic scope). The reading where E_1 scopes over some E_2 is notated as $E_1 > E_2$. E_1's impact on E_2 may be of different kinds. Some examples follow. In (1) teachers may vary with boys; similarly in (2) if scope is used to effect pronoun binding. In (3) negation eliminates existential import. In (4) the Grail need not exist in the actual world. In (5) the polarity item is licensed.

(1) Every boy saw a teacher.
'every boy > a teacher'

(2) Every boy saw the teacher who flunked him.
'every boy > him'

(3) Nobody drew a circle.
'nobody > a circle'

(4) Parsifal seeks the Grail.
'seek > the Grail'

(5) You have not responded yet.
'not > yet'

(6) summarizes Montague's (1974) classical technique for obtaining a reading where *everyone* takes wide scope, binding *his* and inducing referential variation in *a picture*. *Every boy* is interpreted as a generalized quantifier (6b), and a property is formed from the interpretation of its scope (6c). Pictures may vary because they are chosen relative to individuals playing the subject role. Pronoun binding occurs due to the identification of two arguments.

(6a) *Every boy showed his father a picture* [Reading 1] is true if and only if the property (6c) is an element of the set (6b).
(6b) *every boy*: the set of properties every boy has
(6c) *_showed his father a picture*: the property of being an individual such that there exists some picture or other such that this individual showed that picture to this individual's father

(7) restates the right-hand side of (6a) using a logical notation similar to Montague's. Going beyond first-order logic, lambda is the abstraction operator and P a second-order variable over properties.

(7) $\lambda P \forall x[\text{boy'}(x) \rightarrow P(x)](\lambda y \exists z[\text{picture'}(z) \wedge \text{showed'}(y, \text{father-of'}(y), z)])$

Although the operator–variable notation is widely used, it is semantically not essential. For variable-free semantics, see Szabolcsi (1989), Hendriks (1993), Jacobson (1999), and Kruijff and Oehrle (2003).

The intended scope of an expression is often not its sister in the most straightforward constituent structure of the sentence. For example:

(8a) *Every boy showed his father a picture* [Reading 2] is true if and only if the property in (8c) is an element of the set (8b).
(8b) *a picture*: the set of properties some picture or other has
(8c) *every boy showed his father _*: the property of being an individual such that every boy showed this individual to that boy's father

Discrepancies are often resolvable by using a storage mechanism (Cooper, 1983), by positing a more abstract syntactic structure called Logical Form (May, 1985), or by making surface structure more articulated (Kayne, 1998). In other cases substantial semantic considerations or even new interpretive techniques must be invoked.

One semantically significant case is scope independence, exemplified by branching and cumulative readings (Schein, 1993; Hintikka and Sandu, 1997; Landman, 2000):

(9) Some relative of every townsman and some relative of every villager hate each other.

(10) Less than five detectives solved more than six crimes between them.

The main topic of this article is scope dependency. Many of the semantic innovations are necessitated by the observation that different operators have different scoping and binding abilities (Szabolcsi, 1997a). Nominal and adverbial quantifiers are the best studied. At least three classes emerge: (unmodified) indefinites like *some girl, two girls*, distributive universals like *every girl*, and counting quantifiers like *more/less than three girls*. Existential scope and distributive scope are distinguished, and E-type anaphora and covariance with situations are added to traditional bound variable and coreferential readings.

Thus, contrary to the traditional view, scope and binding are not uniform and are not unanalyzable primitives, and the two do not always go hand in hand.

Differential behavior regarding binding was observed first. (All referential dependencies involving pronouns will be indicated by underlining.) Indefinites, but not universals or counting quantifiers, support cross-sentential anaphora. Texts describing scenarios constitute an exception:

(11) A girl is laughing. She is happy.

(12) Every girl is laughing. # She is happy.

(13) More than one girl is laughing. # She is happy.

(14) Every graduate steps forward. The dean shakes hands with him or her.

Indefinites also support sentence-internal anaphora outside their syntactic scope. On the relevant reading both *a donkey* and *it* are within the scope of *every*.

(15) Every farmer who owns a donkey beats it.

These two binding peculiarities inspired varieties of dynamic semantics (Hintikka and Sandu, 1997; Heim, 1982; Kamp and Reyle, 1993; Groenendijk and Stokhof,1991), in which indefinites are associated with referents that outlive the indefinite's syntactic scope. Alternatively, "donkey pronouns" are interpreted as definite descriptions (Evans, 1980; Neale, 1990), and donkey anaphora may be reinterpreted using situation semantics (Heim, 1990; Elbourne, 2001):

(15′) 'every farmer who owns a donkey beats the donkey(s) he owns'
(15″) 'every minimal situation containing a farmer and a donkey he owns extends to one where the farmer beats the donkey'

Büring (2004) extends "situation binding" to other cases where a quantifier binds a pronoun it does not c-command:

(16) Every boy's mother likes him.

(17) Some person from every city likes it.

Indefinites are also special in that their scope within the sentence may escape the containing clause or even island:

(18) Every boy made up a story in which two girls had a bad dream.
'there are two girls such that every boy made up a story in which they had a bad dream'

But such extra-wide scope of indefinites only pertains to their ability to remain referentially independent of higher operators. Like universals and counters, plural indefinites cannot induce referential dependency in higher material. Boys cannot vary with girls in either (19) or (20). Only bad dreams can.

(19) Some boy or other made up a story in which every girl/less than three girls had a bad dream.
* 'for every girl/less than three girls there is a possibly different boy who . . .'

(20) Some boy or other made up a story in which two girls had a bad dream.
* 'for each of two girls there is a possibly different boy who . . .'

This duality cannot be expressed in traditional terms. It necessitates a distinction between existential scope, potentially unbounded, and distributive scope, typically limited to the smallest tensed clause (Beghelli *et al.*, 1997; Reinhart, 1997). Wide existential scope is attributed to referentiality (Fodor and Sag, 1982) or to the existential closure of a choice function variable (Egli and von Heusinger, 1995; Reinhart, 1997). A choice function looks at sets and chooses one element or subset of each. According to Reinhart, the determiner in indefinites is interpreted as a choice function variable, whereas the numeral is a cardinality marker. 0_{choice} *two girls* picks out a set of two girls. Distributivity, if present, is due to the interpretation of the clausemate predicate, e.g., *[each] had a bad dream*.

Extra-wide scoping indefinites may nevertheless be referentially dependent:

(21) Every professor praised every student who reviewed a certain book (that he wrote).
'every professor > a certain book > every student'

Such dependencies have been attributed to intermediate existential closure or to an overt or understood bound pronoun in a maximal-scope indefinite (Skolemized choice functions) (Kratzer, 1998).

Clause-internally, all quantifiers can take existential and distributive scope over material they c-command. Whether inverse scope is possible at all is subject to cross-linguistic variation, and which quantifiers take inverse scope over which others depends on their syntactic hierarchy; therefore these matters are to some extent syntactic. But the classes of quantifiers that behave differently are semantically characterizable (Beghelli and Stowell, 1997; Szabolcsi, 1997b).

Both unmodified indefinites and definites pick out sets undergoing existential closure. As expected from the foregoing discussion, in (22) it is easy to keep the poems fixed (wide existential scope). But triplets of girls only marginally vary with poems, probably because predicates only marginally support inverse distributivity.

(22) Three girls know two poems/these poems/all the poems.

Universals like *every/each girl* readily take inverse distributive scope:

(23) Three girls know each/every poem.

Counting quantifiers may be intersective (*at least n . . .*, *more/less than n . . .*) or proportional (*few . . .*). They do not take inverse scope over universals (24) but they can make higher counters dependent (25):

(24) Every girl knows more/less than three/few poems.

(25) At least one girl knows more than three poems.

It is usually assumed that both universals and counters operate in the manner of generalized quantifiers, see (6b), and the distributivity of universals comes from lexical semantics. Hungarian presents evidence to the contrary. In that language, different types of quantifiers occupy different surface syntactic positions. Interestingly, the comparative quantifier *több, mint n . . .* 'more than n . . .' may occur either in the position of universals or in the position of counters. In the former case its interpretation is necessarily distributive; in the latter case it may be collective. This suggests that the former position has a distributive operator associated with it. *Every girl* is distributive because it only occurs in that position; its own contribution to interpretation is just the set of girls. This set plays a similar role as the one contributed by *two girls*. Counters may be the only quantifiers that truly operate in the manner of (6b). (Bare plurals on the existential reading are not regarded as quantifiers but as kind-denoters or as incorporated predicates.)

Scots

C Macafee, University of Aberdeen, Aberdeen, UK

© 2006 Elsevier Ltd. All rights reserved.

Scots comprises a group of dialects spoken in Lowland Scotland, forming a continuum with Northern English dialects, and in Orkney and Shetland. Scots was taken to Ireland in the 17th century and survived intact there in parts of Northern Ireland and County Donegal. Individual linguistic items also survive in Canada, the United States, and New Zealand. The UK government has given Scots *de facto* recognition by listing it in the European Charter for Regional or Minority Languages, albeit in a section that implies no specific commitments. Ulster Scots is recognized as a language and is given financial support by the UK and Irish governments, under the terms of an intergovernmental agreement.

Scots is in a sociolinguistic continuum with Scottish Standard English (SSE), and is often intermingled with it in practice. Speakers who maintain a rich and focused variety of Scots are found mainly in rural areas and small towns outside the central industrial belt. In the North-East and the Northern Isles, it is not uncommon for professional people to code switch sharply between Scots and English. There are concerns, however, that this ability may not be continuing among younger people. In the most densely populated areas of Scotland, Scots is spoken mainly lower down the social scale.

A question on Scots (parallel to that on Gaelic) was considered for inclusion in the 2001 Census, but it was concluded that a valid and reliable question could not be framed. The question-testing exercises suggested that almost a third of the Scottish population might call themselves speakers of (a dialect of)

Scots

C Macafee, University of Aberdeen, Aberdeen, UK

© 2006 Elsevier Ltd. All rights reserved.

Scots comprises a group of dialects spoken in Lowland Scotland, forming a continuum with Northern English dialects, and in Orkney and Shetland. Scots was taken to Ireland in the 17th century and survived intact there in parts of Northern Ireland and County Donegal. Individual linguistic items also survive in Canada, the United States, and New Zealand. The UK government has given Scots *de facto* recognition by listing it in the European Charter for Regional or Minority Languages, albeit in a section that implies no specific commitments. Ulster Scots is recognized as a language and is given financial support by the UK and Irish governments, under the terms of an intergovernmental agreement.

Scots is in a sociolinguistic continuum with Scottish Standard English (SSE), and is often intermingled with it in practice. Speakers who maintain a rich and focused variety of Scots are found mainly in rural areas and small towns outside the central industrial belt. In the North-East and the Northern Isles, it is not uncommon for professional people to code switch sharply between Scots and English. There are concerns, however, that this ability may not be continuing among younger people. In the most densely populated areas of Scotland, Scots is spoken mainly lower down the social scale.

A question on Scots (parallel to that on Gaelic) was considered for inclusion in the 2001 Census, but it was concluded that a valid and reliable question could not be framed. The question-testing exercises suggested that almost a third of the Scottish population might call themselves speakers of (a dialect of)

Scots, but, in the absence of a popularly accepted terminology, the responses were affected by the form of the question. Urban dialects, which are thinnest in traditional vocabulary, are least likely to be identified with the historical language or to be dignified with the name 'Scots,' and are most likely to be perceived as slang. There is some teaching and research on Scots at university level in Scotland and Northern Ireland, and at the Royal Scottish Academy of Music and Drama in Glasgow. In Northern Ireland, the Ulster Scots Agency supports cultural and linguistic projects, but attempts to promote a hastily modernized version have been met unsympathetically by speakers and nonspeakers alike. In Scotland, a modernized form of Scots ('Lallans') is promoted by the Scots Language Society.

Scots, like Standard English, is descended from the Anglian dialect of Old English. It is not clear to what extent this variety, established south of the Forth in the 7th century, was the ancestor of Scots, and to what extent it was swamped by a later influx of speakers, mainly from Yorkshire. These were followers of Anglo-Norman mercenaries and monastics, invited in by the Scottish crown in large numbers in the 12th century. Anglian spread throughout the Lowlands with the establishment of urban settlements (burghs) and of Norman administration in church and civil life. As a result, Lowland Scots is rich in loans from Old Norse, mostly shared with Northern English dialects. In Caithness, Orkney, and Shetland, where there was extensive Norse settlement, Scots replaced an extinct Scandinavian language, Norn (spoken in Shetland as late as the 19th century). Some loans survive, e.g., *bonxie* 'the great skua' and *moorit* 'brown (of sheep)'. Apart from place-names, Scots texts begin in the 14th century with glosses and phrases in Latin and French documents, and a few legal papers in a Scots are still very similar to Northern English. The long narrative poem, 'The Bruce,' by John Barbour, was written around 1375, but surviving manuscripts are from the early 15th century.

By the 15th century, the orthography of Scots was distinctive. The spellings <ee, oo, ea> were avoided. For /x/, <ch> was used, as in *nicht* 'night'. Words such as 'little' ended in <ill>, thus *litill*. As in Northern English, <quh> was used rather than <wh>, and <sch> rather than <sh>, and there was interchangeability among <u, v, w>, but Scots was unusual in using <w> initially, as in *wp* 'up'. Distinctively, Scots used <lȝ> for French- and Gaelic-derived /ʎ/, as in *tulȝie* 'a struggle', and <nȝ> for similarly derived /ɲ/, as in *cunȝe* 'a coin'. As the retention of these consonants in Early Scots illustrates, the influence of French was independent of its influence on English, and the same was true of Latin, so that loans from these languages further differentiated Scots, as did loans from Middle Dutch (through immigration to the burghs, and fishing and trade contacts), and, of course, loans from Gaelic. The long-term Gaelic influence on vocabulary is, however, unexpectedly small. It would appear that the transition from Gaelic to Scots was effected with some completeness. Gaelic has had phonological influences, e.g., North-Eastern /f/ for /hw/ (earlier /xw/), as in *fa* 'who', and grammatical influences, e.g., emphatic use of reflexives, as in 'It's yoursel!'

In the mid-15th century, Early Scots gave way to Middle Scots (both being stages of Older Scots). Middle Scots saw the spread (from Northern England) of 'i-digraph' spellings for stressed monophthongs—thus <ai>, as in <haim> for <hame> 'home'; <ei>, as in <leid> for <lede> 'lead' (noun or verb); <oi>, as in <rois> for <rose> (the flower); and <ui>, as in <muin> for <mune> 'moon'. As generally north of the Humber, words such as *hame* 'home' have retained a front development of Old English ā, raised by the 'Great Vowel Shift,' and words such as *mune* 'moon' have a fronted development of Old English ō.

Scots and its dialects are characterized by numerous conditioned sound changes. To mention just one dating from this time, there was a vocalization of /l/ following the short vowels /a, o/ and, less regularly, /u/. Examples include *ba* 'ball', pronounced /bɔ/ (Modern Central dialect) or /bɑ/ (Northern dialect); *gowd* /gʌud/ 'gold'; and *fu* /fu/ or *full* /fʌl/ 'full'. A standard based on Edinburgh was emerging when Scots was replaced in formal use by Standard English in the late 16th century, largely as a result of the printing press and of the Reformation of 1560, which introduced the Bible in English translation. Standard English became the speech of the ruling class following the Union of the Crowns in 1603, and of the professions following the Union of the Parliaments in 1707. Insistence that schoolteachers use English began with national inspection in 1845.

Literature and historical documents of all kinds exist from the Older Scots period, including the work of 'makars' such as William Dunbar, Robert Henryson, and Gavin Douglas. Well-known writers from the modern period include Robert Burns, John Galt, Walter Scott, and Robert Louis Stevenson. Folk tales and songs (including the 'muckle sangs,' or Child ballads) have been extensively collected. The 20th-century folk revival has been very important for the continuation of elevated styles of Scots.

Language revival has been a spur to literature, including the poetry of Hugh MacDiarmid (Christopher Grieve), the songs of Hamish Henderson, and drama (original and in translation). Notable work continues

also in local vernaculars – for instance, in the poetry of Sheena Blackhall in North-East Scots ('the Doric'). The urban dialects, being thinner, are more widely accessible, as witness the work of Liz Lochhead, Tom Leonard (both Glasgow), and Irvine Welsh (Edinburgh). Scots, when it is occasionally used in television and radio scripts, is generally thin, for the same reason.

Modern Scots (from 1700 on) has preserved little from Older Scots in orthography, apart from <ch> and <ui> spellings. The 18th-century introduction of <oo> for /ø/, as in /tøm, tɪm/ 'empty', though now replaced by <uCe, ui>, still causes some confusion in spelling and pronunciation in historical contexts. Apostrophes for 'missing' letters, such as for /d/ after /n/, as in *en'* 'end', or /d/ after /l/, as in *aul'* 'old', and for final <th>, as in *wi'* 'with', were also a feature of Modern Scots, but have largely been dropped as the result of spelling reform. The following example is of Modern Central Scots:

> The laddies gets hame fae the schule afore the wee lass an they wint their tea the meenit they're in the hoose. Bit it'll no dae thaim a scart o herm tae thole their hunger a while langer.
> ðɪ 'ladez gɪts 'hem fe ðɪ 'skɪl ʌ'for ðɪ 'wi 'las n̩ ðe 'wɪnt ðɪr 'ti ðɪ 'minɪt ðɪr ɪn ðɪ 'hus. bɪt ɪtl̩ 'no 'de ðʌm ʌ 'skart ɪ 'hɛrm te 'θol ðɪr 'hʌŋɪr ʌ 'hwəil 'laŋɪr.

Scots has minor differences in grammar from English dialects; for instance, there is a double system of concord in the present tense of verbs: if the subject is a personal pronoun adjacent to the verb, the verb is inflected only in the third-person singular (and second-person singular, where it is preserved), otherwise in all persons and numbers. The dialects of Orkney and Shetland preserve the second-person singular, as in *du* 'thou'. A new second-person plural form, *youse*, has spread from Ulster to Glasgow. In the demonstrative system, *yon* (or *thon*) expresses a greater distance than does 'that' or *thae* 'those'.

The vowel length of stressed monophthongs (other than /ɪ, ʌ/, which are always short) is determined by the Scottish Vowel-Length Rule, with long vowels before the voiced fricatives /v, ð, z, ʒ/ and /r/, and morpheme finally, thus *agreed* long but *greed* short (likewise in SSE for a narrower range of vowels). Old English ū remains /u/, as in *aboot* 'about' and *hoose* 'house'. Old English ō fronted to /ø/ remains in conservative dialects (mainly Orkney and Shetland), as in 'do' (from Old French), 'use' and *schule* 'school'. In North-East Scots, this unrounded already in Middle Scots to /i/, thus *dee*, *meen*, and *eese*. In Modern Central Scots, the vowel unrounds in the long environments of the Scottish Vowel-Length Rule to /e/, thus *yaise* (verb), and to /ɪ/ elsewhere, thus *yis* (noun). In some dialects, this /ɪ/ from earlier /ø/ remains separate from the reflex of Old English /i/, as in 'bring', which is lower and more central, as [ë]. This may be the source of the similar realization of /ɪ/ in New Zealand English.

Old English ī has split in Modern Scots into /aɪ/ in the long environments of the Scottish Vowel-Length Rule, as in 'five' and 'why', and into /əi/ otherwise, as in 'while'. (The similar allophony in Canadian English may owe something to Scots or to SSE.) This /əi/ merges with the reflex of *ai* word finally, as in *cley* 'clay', and in Anglo-Norman *ui*, as in *bile* 'boil'. The unrounding of ŭ to /ʌ/ is complete: there is no /ʊ/. Thus 'push' and 'pull' have /ʌ/. As a consequence of the Scottish Vowel-Length Rule, the short vowel /o/, as in 'lot', *tod* 'fox' has merged in Central Scots with the long vowel /o/, as in *thole* 'endure' (from Old English ŏ by Open Syllable Lengthening).

The vowel phonology of SSE is largely based on the vowel system of Central Scots, but with the lexical incidence of Standard English. In the circumstances of the 18th century, with limited access to native speakers of English, a number of interdialectal features became fixed in SSE. Since there was no /ʊ/, these words were assigned to /u/, thus 'pool' and 'pull' are homophones in SSE. (In Central Scots, they are /pɪl/ and /pu/ or /pʌl/.) Similarly, since there was no /ɒ/, words such as 'cot' were assigned to Central Scots /ɔ/, as in *lauch* 'laugh' and *saut* 'salt'. Thus 'cot' and 'caught' are homophones in SSE. (In Central Scots, they are /kot/ and /kɔxt/; in Northern Scots, they are /kɔt/ and /kɑxt/.) The similar absence of distinction between the vowels of 'cot' and 'caught' in some North American varieties may owe something to SSE. The lower and more central realization of /ɪ/ in Scots has left a residue of words in SSE with a phoneme /ë/, thus /nëvər/ 'never', contrasting with /rɪvər/ 'river' and /sɛvər/ 'sever'.

Scots has a large shared vocabulary with English (for example, 'the,' 'cat,' and 'tell') and also much distinctive vocabulary, as in the Old English survivals *neep* 'turnip' and *een* 'eyes', the coinages *gully* 'knife' and *tapsalteerie* 'head-over-heels', Old Norse *nowt* 'cattle' and *skellie* 'squint', Middle Dutch *craig* 'the neck' and *redd* 'clear up', Anglo-Norman *leal* 'loyal' and *hurcheon* 'hedgehog', Latin *stravaig* 'roam', Central French *Hogmanay* 'New Year's Eve', and Gaelic *corrie-(fistit)* 'left-(handed)' and *sonse* 'prosperity'.

Scots Gaelic

K MacKinnon, University of Herefordshire, Black Isle, UK

© 2006 Elsevier Ltd. All rights reserved.

Origins and Early History

The Scottish people originated with Gaelic-speaking incomers from northeastern Ulster who settled in the northwestern coastlands and islands of Caledonia in the later 5th century and subsequently relocated their kingdom of Dal Riata from Ulster to Argyll, 'the coastland of the Gael' (Bannerman, 1974). This community subsequently grew by absorption of the Picts in the east and the conquest of the Britons and Angles in the south into what came to be called Scotland by the 11th century. Viking settlements in the Northern Highlands and Northern Isles from the end of the 8th century established the Norn language, which survived in Caithness, Orkney, and Shetland until the 18th century.

Under the kingship of Malcolm III, 'Ceannmòr' (1054–1096) Gaelic began to lose its pre-eminence at court and among the aristocracy to Norman French and in the Lowland area to the Anglian speech of the burghs, which were established first in eastern Scotland by David I (1124–1153). This speech was known first as Inglis and later as Scots, and it rapidly became the predominant language of the Scottish Lowlands. However, Gaelic was maintained until the later Middle Ages in Galloway and Carrick in the southwestern Lowlands, reputedly finally ceasing in Ayrshire in the 18th century.

Linguistic Characteristics of Scottish Gaelic and its Dialects

Scottish Gaelic (Scots Gaelic) is a Celtic language, a member of the Goidelic or 'Q-Celtic' branch, closely related to Irish and Manx. It is basically a VSO language: sentences typically begin with the verb, followed by the subject and the object. Adjectives generally follow the noun. As with other Celtic languages, personal pronouns combine with prepositions and decline for person. Verbs do not generally decline for person, and there are only 10 irregular verbs.

There are two forms of the verb 'to be'. *Bi* is the basic form for straightforward statements. It conjugates fully for tense and combines with the present participle of other verbs to form continuous tenses. The emphatic form of the verb 'to be' *is* exists only in the present-future and past tenses. These two verbs, together with prepositions and prepositional pronouns, enable a vast array of idioms to be formed, which enable actions in the 'real world' to be grammatically distinguished from abstract, mental, psychic, and emotional states.

There are many English loanwords, such as *ad* (hat), *barant(as)* (warrant), *breacaist* (breakfast), *brot* (broth, soup), *comhfhurtail* (comfortable), *geata* (gate), *mionaid* (minute of time), *paidhir* (pair), *rathad* (road), *stràid* (street), and *targaid* (target). Direct borrowings from Latin include *aingeal* (angel), *airgiod* (silver, money), *crois* (cross), *eaglais* (church), *Ifrinn* (Hell), *feasgair* (evening), *gineal* (offspring), *manach* (monk). Substantial contact with

Origins and Early History

The Scottish people originated with Gaelic-speaking incomers from northeastern Ulster who settled in the northwestern coastlands and islands of Caledonia in the later 5th century and subsequently relocated their kingdom of Dal Riata from Ulster to Argyll, 'the coastland of the Gael' (Bannerman, 1974). This community subsequently grew by absorption of the Picts in the east and the conquest of the Britons and Angles in the south into what came to be called Scotland by the 11th century. Viking settlements in the Northern Highlands and Northern Isles from the end of the 8th century established the Norn language, which survived in Caithness, Orkney, and Shetland until the 18th century.

Under the kingship of Malcolm III, 'Ceannmòr' (1054–1096) Gaelic began to lose its pre-eminence at court and among the aristocracy to Norman French and in the Lowland area to the Anglian speech of the burghs, which were established first in eastern Scotland by David I (1124–1153). This speech was known first as Inglis and later as Scots, and it rapidly became the predominant language of the Scottish Lowlands. However, Gaelic was maintained until the later Middle Ages in Galloway and Carrick in the southwestern Lowlands, reputedly finally ceasing in Ayrshire in the 18th century.

Linguistic Characteristics of Scottish Gaelic and its Dialects

Scottish Gaelic (Scots Gaelic) is a Celtic language, a member of the Goidelic or 'Q-Celtic' branch, closely related to Irish and Manx. It is basically a VSO language: sentences typically begin with the verb, followed by the subject and the object. Adjectives generally follow the noun. As with other Celtic languages, personal pronouns combine with prepositions and decline for person. Verbs do not generally decline for person, and there are only 10 irregular verbs.

There are two forms of the verb 'to be'. *Bi* is the basic form for straightforward statements. It conjugates fully for tense and combines with the present participle of other verbs to form continuous tenses. The emphatic form of the verb 'to be' *is* exists only in the present-future and past tenses. These two verbs, together with prepositions and prepositional pronouns, enable a vast array of idioms to be formed, which enable actions in the 'real world' to be grammatically distinguished from abstract, mental, psychic, and emotional states.

There are many English loanwords, such as *ad* (hat), *barant(as)* (warrant), *breacaist* (breakfast), *brot* (broth, soup), *comhfhurtail* (comfortable), *geata* (gate), *mionaid* (minute of time), *paidhir* (pair), *rathad* (road), *stràid* (street), and *targaid* (target). Direct borrowings from Latin include *aingeal* (angel), *airgiod* (silver, money), *crois* (cross), *eaglais* (church), *Ifrinn* (Hell), *feasgair* (evening), *gineal* (offspring), *manach* (monk). Substantial contact with

Norse produced *faodhail* (ford, crossing, from Norse *vadhil*), *gocaman* (lookout, from Norse *gokman, gauksman*), *sgalag* (lackey, from Norse *skalkr*), *sgioba* (crew, from Norse *skip*), and *uinneag* (window, from Norse *windauga)* (MacBain, 1982: 163, 200, 310, 315, 386).

Pre-aspiration in present-day Scottish Gaelic dialects occurs before the final vowels in such words as *mac* (son, pronounced as if *mahk*), *sop* (wisp, pronounced as if *sohp*), and *sloc* (pit, pronounced as if *slohk*). This is very typical of southwest Norwegian dialects and northwestern Scottish Gaelic dialects (Marstrander, in Geipel, 1971). Historically, Scottish Gaelic dialects in the northwest with its islands were very different from dialects in the east-central and eastern Highland areas. The latter are today well nigh extinct—and all mainland dialects are moribund. Eastern dialects did not diphthongize the long 'e' in words like *meud* (measure, pronounced *meeutt*) or *beul* (mouth, pronounced *beeal*) or intrude 's' between final 'r' and 't' in words like *tart* (thrirst, pronounced *tarst*), *neart* (strength, pronounced *nyarst*), etc. Similarly, the northwestern dialects intrude 't' between initial 's' and 't' as in *sruth* (stream, current, pronounced *strooh*) and *srath* (strath, wide valley, pronounced *strah)*.

As with Irish, Scottish Gaelic observes the spelling convention of *caol ri caol is leathan ri leathan* (narrow to narrow and broad to broad). Where a narrow vowel 'i' or 'e' occurs before a consonant, it must be followed by a narrow vowel. Where a broad vowel 'a,' 'o,' or 'u' occurs before a vowel, it must again be followed by a broad vowel. Pronunciation of consonants is determined by the surrounding vowels; that is, the consonants thus flanked by narrow or broad vowels are regarded as correspondingly 'narrow' or 'broad' and pronounced accordingly. For example, *feasgar* (evening, afternoon) is pronounced as *fessgar*, where the first *a* is silent but helps render the consonants as 'broad.' Another example is *seillean* (bee), where the first *o* renders the initial *s* as narrow and pronounced as *sh*, and the *i* and second *e* renders the *ll* narrow and pronounced with the tongue to the front of the palate.

Gaelic uses only these letters: *a b c d e f g i l m n o p r s t u*. The letter *h* is not regarded as a regular letter. No words begin with it, except Norse-derived place names, such as *na Hearadh,* (Harris); it never stands alone in spelling, except in combination with another consonant to signify distinctive phonemes or before words beginning with vowels (e.g., *bun na h-aibhne*, the foot of the river) or to indicate aspiration or lenition in grammatical change for gender, tense, case, or word combination.

History: Medieval to Modern

By the later Middle Ages, Gaelic had retreated to the Highlands and Hebrides, which maintained some degree of independence within the Scottish state. Attempts were made by legislation in the later medieval and early modern period to establish English at first among the aristocracy and increasingly among all ranks by education acts and parish schools. The Scots Parliament passed some ten such acts between 1494–1496 and 1698. The Statutes of Iona in 1609–1610 and 1616 outlawed the Gaelic learned orders and sought to extirpate the 'Irish' language so that the "vulgar English tongue" might be universally planted (MacKinnon, 1991). The suppression of the Lordship of the Isles (1411), the Reformation (1560), the final failure of the Jacobite cause (1746), and the end of the clan system were all in turn inimical to Gaelic.

Further setbacks for the language were brought about by the loss of life in the Napoleonic Wars, the ensuing Highland Clearances, the potato famine in the 1840s, and economic marginalization and underdevelopment that engendered large-scale migration to the Lowlands and overseas. Some mitigation resulted from legislation following the 'Crofters' Wars' in 1886, and at the end of the 19th century Gaelic was still the predominant language throughout the mainland Highlands and Hebrides.

In World War I, losses of life at sea and in the armed forces took a considerable toll on the Gaelic population, and the interwar period witnessed renewed emigration, especially from the Hebrides. The numbers of Gaelic speakers declined precipitately from 254 415 in 1891 to 58 969 in 2001. Because of internal migration from the Highlands and Islands to the Lowlands, 45% of all Gaelic speakers today reside in Lowland, in urban Scotland.

Gaelic in Present-Day Society: Cultural and Administrative Infrastructure

Although only 93 282 (1.84%) of Scotland's 5 062 011 population had any sort of oral, literate, or comprehension abilities in Gaelic in 2001 (GROS, 2001 Census), speakers and supporters have made increased demands for the use of Scottish Gaelic in education, broadcasting, and the arts, and have advocated for official recognition of the language. There was some presence of Gaelic from the earliest years of radio and on television since the mid-20th century. However, radio output of Scottish Gaelic greatly increased with BBC Radio nan Gàidheal from the mid-1980s, and a more realistic television budget from the early 1990s led to its increased use on

television. Now there are demands for 24-hour daily radio provision and a dedicated digital television channel in Scots Gaelic.

Gaelic has been taught as a specific subject in some Highland and Island schools since the early 20th century, and bilingual education started in the early primary stages in Gaelic areas in the late 1950s. Although a more all-through model was introduced in the Western Isles from 1975, it has not yet really produced a satisfactorily bilingual secondary stage. Gaelic medium primary education began in 1985 after a successful Gaelic preschool initiative (*Comhairle na Sgoiltean Àraich*/CNSA from 1982) in two schools at Inverness and Glasgow. By 2004, the number of schools had grown to 60, with some 1972 pupils. In the secondary stage, 36 schools were teaching 974 fluent speakers, and 14 schools had Gaelic medium streams with 284 pupils. A Gaelic higher education college, *Sabhal Mor Ostaig*, was established in 1972, offering diploma courses taught through Gaelic since 1983, and a range of Gaelic medium degree courses have been offered within the developing University of the Highlands and Islands since 1998. Although these provisions have produced some small growth in the numbers of young people with Gaelic abilities, these efforts have been clearly insufficient in stabilizing Gaelic numbers overall or in reversing language shift.

Over the past 30 years, the Gaelic cultural scene has been enriched by the growth of theater and television production companies. They have been greatly assisted by funding from the Scottish Arts Council, the Gaelic arts agency *Proiseact nan Ealan* (from 1987), the Gaelic Television (now, Broadcasting) Fund, and Gaelic Media Services and its predecessors from 1992. These have drawn upon a wealth of traditional culture, including folk songs and vernacular verse. These genres have grown in Gaeldom out of the suppression of the bardic schools in the early 17th century and are still viable today. The more formal verse of the bardic period and later is well represented in current publications, as are more recent genres, such as plays and the novel. These have been assisted since 1968 by the Gaelic Books Council. The Gaelic cultural organization, *An Comunn Gàidhealach* (The Highland Association), was founded in 1891 and has run a national cultural festival, the Royal National Mod, from 1892. More recently, a local Gaelic folk festival *Fèis Bharraigh* (1980/81) has developed into a national organization, *Fèisean nan Gàidheal,* which organizes local and national Gaelic cultural festivals.

The end of the 20th century witnessed much enhancement of cultural infrastructure for Gaelic, with organizations for Gaelic learners (CLI from 1982), pre-school education (CNSA from 1982), Gaelic parents (*Comunn nam Parant*, from 1983), and language development (*Comunn na Gàidhlig* [CNAG] from 1984). These bodies have called for further resources for the language, have commissioned studies and reports, and have advocated for its official recognition and status. The 1997 Labor Government appointed a Minister for Gaelic and set up the Milne Gaelic Broadcasting Taskforce from 1997–2000. The Scottish Executive set up two more commissions: the Macpherson Taskforce on Public Funding of Gaelic (1999–2000), and the Ministerial Advisory Group on Gaelic (MAGOG; 2000–2002). These have resulted in improved provisions for Gaelic education, calls to improve Gaelic media provision, the establishment of a Gaelic Language Board, *Bord na Gaidhlig,* and the introduction of a Gaelic Language Bill in 2003. With these developments, there has been an emphasis on research, and the application of such ideas as language planning, secure status, and reversing language shift (MacKinnon, 2004). New ideas and policy objectives have emerged in the new millennium. The future of Gaelic as a continuing language of home and community very much depends upon their outcome.

Scots Lexicography

C Macafee, Dyce, Aberdeenshire, UK

© 2006 Elsevier Ltd. All rights reserved.

The long tradition of Scots lexicography is discussed by Murison (1987) and Aitken (1989), themselves senior editors of *The Scottish National Dictionary* (SND) and *A Dictionary of the Older Scottish Tongue* (DOST), respectively. Aitken identifies three historical strands: glossaries to Older Scots texts, notably Ruddiman's (1710) glossary to Gavin Douglas's *Æneid*; glossaries to contemporary works, notably Robert Burns's own enlarged glossary to the 1787 edition of his *Poems*; and lists of scotticisms (as a guide to avoiding them), of which Beattie's (1787) is the first to be arranged alphabetically. The first full-scale etymological dictionary of Scots was Jamieson's (1808, 1825, with subsequent supplements and editions).

There are now two authoritative multivolume historical dictionaries, each the culmination of generations of scholarship. Conceived as extensions to *The Oxford English Dictionary* (OED), DOST, begun by Sir William Craigie (of the OED), covers the period up to 1700; and SND, begun by William Grant, covers the period from 1700 onwards. These have now also been published on-line as the *Dictionary of the Scots Language*.

The Concise Scots Dictionary (CSD) is a digest of SND and DOST. Its pronunciation entries are more systematically phonemic than those of SND. The *Scots thesaurus*, based on CSD, covers about half of its vocabulary. Other dictionaries in the Scottish Language dictionaries range include *The Concise English-Scots Dictionaries*.

Collins Gem Scots Dictionary is an independent work, treating current vocabulary.

All dictionaries of modern Scots, up to and including SND and CSD, omit material shared with Standard English, which can give the impression that Scots consists only of what is uniquely Scots. But Scotsmen and women were also active in the fields that yielded increases in Modern English vocabulary. It was to make just this point that Murison added an appendix to SND containing "A list of scientific terms with Scottish connections."

DOST includes vocabulary shared with Standard English, but both DOST and SND omit etymologies for items found also in Standard English in some form or sense.

Some other works should be borne in mind as sources of information about Scots vocabulary. The *Middle English Dictionary* can be useful for comparison, particularly in the poorly documented period of Scots before c. 1375. Although SND and DOST supercede, for Scots, both OED and *The English Dialect Dictionary* (of which Warrack (1911) was a spin-off), these can still supply independent selections of quotations.

The lexical volumes of *The Linguistic Atlas of Scotland* (Vols. I and II) were not incorporated into SND, and have some additional items.

Ulster is not well covered in SND, so Fenton (2000) and *A Concise Ulster Dictionary* both add to the record. The SND omits the slang component of the language almost entirely, apart from a few items labeled 'Glasgow slang.' *A Dictionary of Slang and Unconventional English* and the *Dictionary of the Underworld* are useful supplements, as is Munro's (1996) Glasgow compilation. Otherwise, the main value of dialect dictionaries published subsequent to SND is to sift out the material that is still current. Lamb (1988) and Fenton (2000) are particularly well focused in this respect.

Scripts, Undeciphered

B Wells, Harvard University, Cambridge, MA, USA

© 2006 Elsevier Ltd. All rights reserved.

> Every written document not only embodies the message 'I am meant to be read' but also instructions, however indirect, as to how this can be done. In other words, the systematic makeup of writing contains a key to its own decipherment (Coulmas, 2003).

The act of decipherment is one of reconstructing the reading instructions of a writing system from what remains of it hundreds, more often thousands, of years after it has no longer been in use. In the case of ancient scripts, what remains are normally fragments of the entire written record of the system, often with little other information to help. For this reason several ancient scripts remain undeciphered.

Linear A

Linear A script has about 1500 texts with 7500 characters. The texts are found in archaeological deposits in Crete, Greece, and Western Anatolia; they date to 1750 to 1450 B.C. Examples of the script are found on seals, tablets, and pottery. The first step toward the decipherment of Linear A occurred in 1950 with the decipherment by E. L. Bennett Jr. of the number system (including fractions). From the sign list it would seem to be a logosyllabic script.

There is a strong graphic resemblance between 60% of the Linear B phonetic (syllabic) signs and signs in the Linear A script (Robinson, 2002: 191). There is also some resemblance between a small number of Linear B logographs and some Linear A signs. This fact, and the fact that these two scripts are found in the same area and even in the same deposits, would lead us to believe that decipherment of Linear B would lead to the decipherment of Linear A – but it does not. The Linear A decipherment is a similar case to the Meroitic decipherment, where the words can be read but the root language is unknown. Meroitic sign values are known from their Egyptian hieroglyphic equivalents, but the words are not from a recognizable language. For Linear A, however, the values of the signs are not as certain. Several root languages have been suggested: Semitic family (nearly universally rejected), some form of Greek (disputed and unlikely), and Lycian (Robinson, 2002: 198–199). The case for Lycian is unproven, but it seems the most likely candidate given the data at hand. Linear A remains undeciphered, but active archaeological research in the area raises the possibility of further finds and keeps hope alive.

Proto-Elamite

The Proto-Elamite script was used on the Iranian Plateau and at Susa from 3050 to 2900 B.C. There are 1500 known texts bearing about 100 000 characters. The sign list contains 600–900 or so graphemes, indicating a logosyllabic script. As for Linear A the number system is well understood, and some logographs have known semantic values derived from comparisons with Proto-Cuneiform, but the overlap is only about 1%. There is no cultural continuity between the Proto-Elamite and later Elamite writing (Linear and Cuneiform), and so these systems cannot be used in attempted decipherments (Potts, 1999). As the root language is still unknown and the vast majority of nonnumerical signs cannot be read, Proto-Elamite remains undeciphered. "The prospects of discovering script characters that could lead to a decipherment of Proto-Elamite are not great, but there are some areas of promise" (Englund, 2001: 29). Englund believes that the statistical analysis of the text might lead to the identification of the root language and eventually to a decipherment. This work is still in progress, but early results seem promising.

The Indus Script

The Indus script is found inscribed on objects over a vast region of South Asia, but the Indus heartland is in

There is a strong graphic resemblance between 60% of the Linear B phonetic (syllabic) signs and signs in the Linear A script (Robinson, 2002: 191). There is also some resemblance between a small number of Linear B logographs and some Linear A signs. This fact, and the fact that these two scripts are found in the same area and even in the same deposits, would lead us to believe that decipherment of Linear B would lead to the decipherment of Linear A – but it does not. The Linear A decipherment is a similar case to the Meroitic decipherment, where the words can be read but the root language is unknown. Meroitic sign values are known from their Egyptian hieroglyphic equivalents, but the words are not from a recognizable language. For Linear A, however, the values of the signs are not as certain. Several root languages have been suggested: Semitic family (nearly universally rejected), some form of Greek (disputed and unlikely), and Lycian (Robinson, 2002: 198–199). The case for Lycian is unproven, but it seems the most likely candidate given the data at hand. Linear A remains undeciphered, but active archaeological research in the area raises the possibility of further finds and keeps hope alive.

Proto-Elamite

The Proto-Elamite script was used on the Iranian Plateau and at Susa from 3050 to 2900 B.C. There are 1500 known texts bearing about 100 000 characters. The sign list contains 600–900 or so graphemes, indicating a logosyllabic script. As for Linear A the number system is well understood, and some logographs have known semantic values derived from comparisons with Proto-Cuneiform, but the overlap is only about 1%. There is no cultural continuity between the Proto-Elamite and later Elamite writing (Linear and Cuneiform), and so these systems cannot be used in attempted decipherments (Potts, 1999). As the root language is still unknown and the vast majority of nonnumerical signs cannot be read, Proto-Elamite remains undeciphered. "The prospects of discovering script characters that could lead to a decipherment of Proto-Elamite are not great, but there are some areas of promise" (Englund, 2001: 29). Englund believes that the statistical analysis of the text might lead to the identification of the root language and eventually to a decipherment. This work is still in progress, but early results seem promising.

The Indus Script

The Indus script is found inscribed on objects over a vast region of South Asia, but the Indus heartland is in

modern-day Pakistan and northwest India. Since its discovery, the Indus script has presented a challenge to epigraphers. The sign distributions are highly patterned, and that there is structure in the texts is obvious to all those who have worked with them. At least 2500 Indus texts have been available for study since 1940 (Marshall, 1931; Mackay, 1938; and Vats, 1940). These circumstances have led to a series of attempted decipherments using a variety of different methodologies. The results have been as varied as the number of would-be decipherments (Possehl, 1996: 76–161, lists the 60 most important). Several facts have emerged from these decipherments. The first is that no two decipherments agree on sign values, even when they are assuming the same root language. The second fact is that there is no agreement on the details of the Indus sign list. Sign lists vary in length from 62 (Rao, 1973) to 615 (Wells, 2000). Third, beyond a general agreement that the texts are mostly read from right to left, there is little agreement as to the mechanics of the script. In fact, with some notable exceptions (Knorozov, 1968; Lal, 1975; Parpola, 1994; Bonta, 1995; and Wells, 2000), little attention has been paid to sign distributions and macro structures (syntax) in the texts. Decipherments have suffered from a lack of typological, temporal, and geographic control (Kelley and Wells, 1995). That is, they generally lump all texts into a single analytical group without regard for the type of artifact the text was inscribed on, the site of origin, or the age of the artifact. This methodology has yielded contradictory and confusing results. This is especially true of decipherments that rely on very general sign lists, which have the effect of systematically removing detail of sign relationships from the texts (Knorozov, 1968; Mahadevan, 1970; and Parpola, 1994) and in some cases creating relationships that do not exist between signs (Parpola, 1994).

The Indus script has about 600–700 signs, indicating a logosyllabic system. While there are 5644 seals and other artifacts associated with the Indus civilization, only 3821 of these have at least one recognizable Indus sign (totaling 18 680 characters). The Indus script has resisted decipherment for over 75 years, and there are several good reasons for this:

1. No bilingual
2. Unknown language
3. No long texts
4. Unknown type of script
5. Poor chronological control
6. No adequate corpus
7. No comprehensive sign list.

As things stand, nothing can be said about the language(s) of the Indus people that is not tentative or speculative. To further complicate this issue, the possibility exists that within the boundaries of the Indus Civilization more than one language was spoken and written in antiquity.

So is the Indus script undecipherable? The only hope for a decipherment lies in the identification of the root language of the Indus script through the structural analysis of the texts. This research is currently under way at Harvard University, and the forthcoming results may answer this question.

Rongorongo (Rapanui) Writing

Father Joseph-Eugene Eyraud was the first foreign resident of Rapanui (Easter Island). Father Eyraud wrote in 1864, "One finds in all the houses wooden tablets or staff covered with sorts of hieroglyphic characters" (Fischer, 1997: 11). The many wooden objects inscribed with Rongorongo were apparently used as firewood in the year 1865. The conversion of the Rapanui to Christianity and the scarcity of wood combined to motivate this sudden and nearly complete destruction of the written records of their history and religion.

The age of Rongorongo is not easily determined. Estimates range from before 500 A.D. to after European contact. The early estimate is based on a Rapanui story that the first settler (Hotu Matu) arrived with 67 tablets. In truth, the origin of the script cannot be convincingly argued. The development of a complex script for which only rare examples are known, and for which most of the details of its history and meaning are lost, cannot be easily resolved. This issue bears directly on the decipherment of the script. The subject matter of the texts and the identification of what the signs represent are of immeasurable assistance in the decipherment of the texts.

As to the Rapanui people: In 1770 there were an estimated 4000 people living on Easter Island. In 1862 and 1863, somewhere between 1000 and 2000 Rapanui were carried off as slaves to Peru; few returned. Father Zumbohm tells us that in 1866 so many Rapanui died from disease that it was no longer possible to bury them. Included among the dead was Vike, the last Rongorongo expert (Fischer, 1997: 9). By 1868 only about 900 Rapanui were left on Easter Island (Fischer, 1997: 20), and none were literate in the indigenous writing system.

The Rongorongo script is found inscribed on 26 artifacts from Easter Island. These inscriptions contain 14 083 signs arranged in 314 lines. There are about 120 basic signs in Rongorongo that can stand alone, or be combined to form more complex signs. These combinations can take the form of a simple ligature, a compound ligature, or what Barthel called fusions. For anthropomorphic signs, the combination

of heads, arms, legs, and other elements allows the creation (spelling) of sign clusters (words). The script is read left to right. This reading order is based on statements by three different informants made in 1873, 1886, and 1914 (Fischer, 1997: 349). Texts are read beginning at the bottom left of the tablet and the tablet is rotated 180 degrees after each line is read. In other words every second line is inverted. The tablets are read ascending on the obverse and descending on the reverse. Every Rongorongo artifact with more than one line of text uses the inverse boustrophedon method.

Fischer (1997) gives account of 50 individual attempts to decipher Rongorongo, some more serious than others. The most famous and creditable attempt at decipherment was made by Barthel (1958). Barthel gives the first comprehensive sign list and the first full set of credible drawings. His decipherment was based on a methodology that relied in part on the analysis of parallel passages. Barthel also performs counts of frequencies for all signs and grouping of signs, which is useful in the analysis of ligatures and the identification of words respectively. One result of Barthel research was the identification of the 120 basic signs of Rongorongo. There is a possibility that this script is syllabic, as Rapanui has complex vowels and glottal stops, it would require about 120–130 syllables to express the language. While Barthel (1958) did not decipher Rongorongo, he did nevertheless make a huge contribution to the field. His drawings, sign list, statistical analysis, and identification of the count of moons section of the Mamari tablet add immeasurably to our understanding of Rongorongo.

Minor Scripts

Minor scripts are those scripts present in few texts (sometimes only one), where the language is unknown, the exact sign inventory is unknown, and consequently the prospects for decipherment are not good. The Phaistos disk and Byblos pseudohieroglyphic are both examples of this class of writing. Daniels (1996: 29–30) provides a description of Byblos pseudo-hieroglyphic: The ancient city of Byblos has yielded a handful of enigmatic texts in an unknown script of which the most extensive are two on bronze tablets. The 1038 characters found on them can be classified into 114 signs. There have been four significant attempts at decipherment – none successful.

The Phaistos disk is a unique item not just because it is the only example of this system, but also because the text was apparently made with stamps of the individual signs. It dates to 1850–1600 B.C. and contains 242 characters using 45 different signs. Little can be said about this script except that it exists, and more examples are needed before there can be any hope of a decipherment.

Sebeok, Thomas Albert (1920–2001)

M Danesi, University of Toronto, Ontario, Canada

© 2006 Elsevier Ltd. All rights reserved.

Over his illustrious career as semiotician and linguist, Thomas A. Sebeok contributed significantly to the shaping of ideas and practices within the two interrelated fields. He brought not only outstanding scholarship to both, but also an enthusiasm and joy that made them interesting in and of themselves. By his own admission, Thomas Sebeok was not the prototypical scholar, one who takes on a narrow topic and studies it to its most profound depths. Rather, he liked to characterize himself as an 'academic bee,' who darted around from flower to flower, sipping nectar, gathering pollen from flowers, serendipitously fertilizing whatever he touched. His intellectual curiosity, amazing working capacity, and ease of writing would yield more than 450 books and articles.

Sebeok was born in Budapest in 1920. After a brief stay in England, he immigrated to the United States. He earned a Ph.D. in oriental languages and civilizations at Princeton, after studying at the University of Chicago under Charles Morris (1901–1979) and Leonard Bloomfield (1887–1949). He also commuted to Columbia to pursue his studies of linguistics under the tutelage of Roman Jakobson (1896–1982), who later became his dissertation director and whose broader views on the place of language within the humanities and social sciences would shape Sebeok's intellectual development.

In 1943 Sebeok went to Bloomington to teach in the Army Specialized Training Program in foreign languages during World War II. As enrollment swelled into the thousands and the number of less-taught tongues rose to 15, he took over the helm of the program. At war's end, he was assigned to teach courses in English composition and world literature in the department of English, broadening his domain of expertise by conducting fieldwork on the Wisconsin Winnebago and the Bolivian Aymar. He subsequently created and chaired the Program in Uralic and Altaic Linguistics, laying the groundwork for what was to become a leading center for research and graduate training on the peoples of Central Asia as well as on the Mongolian and Tibetan languages.

Sebeok's trailblazing in the various language sciences and arts established him as a leading scholar at Bloomington throughout the 1950s and 1960s, where he founded the famous Research Center for Language and Semiotic Studies and edited the journal *Semiotica* from its inception in 1969 until his death in 2001. Sebeok's intention was to give semiotics an autonomous disciplinary niche in the academic landscape rather than being perceived merely as a set of idiosyncratic techniques and loose concepts. For his pivotal efforts he was honored with the presidency of the Linguistic Society of America and of the International Association of Semiotic Studies.

Among Sebeok's most important books, the following stand out: *The sign and its masters* (1979), *The play of musement* (1981), *Contributions to the doctrine of signs* (1985), *A sign is just a sign* (1991a), *Semiotics in the United States* (1991b), and *Signs: an introduction to semiotics* (1994), *The forms of meaning* (with Danesi, 2000), and *Global semiotics* (2001). An overall assessment of his life and work can be found in the excellent booklet by Petrilli and Ponzio (2001). A retrospective of his ideas and his contributions to semiotics can be found in the anthology edited by Danesi (2001). Sebeok's place in the history of semiotics has been taken up by John Deely (2001) in his monumental historiography of semiotics.

Sebeok's main claim to fame was his work on animal communication and on the biological basis of the sign. He argued that the central goal of semiotics can be condensed, essentially, to figuring out how signs model reality in species-specific ways. Model making typifies all aspects of human intellectual and social life, Sebeok argued, constituting a truly astonishing evolutionary attainment, without which it would be virtually impossible for humans to carry out their daily life routines. All this suggested to him the presence of a 'modeling instinct' that is to human mental and social life what the physical instincts are

An overall assessment of his life and work can be found in the excellent booklet by Petrilli and Ponzio (2001). A retrospective of his ideas and his contributions to semiotics can be found in the anthology edited by Danesi (2001). Sebeok's place in the history of semiotics has been taken up by John Deely (2001) in his monumental historiography of semiotics.

Sebeok's main claim to fame was his work on animal communication and on the biological basis of the sign. He argued that the central goal of semiotics can be condensed, essentially, to figuring out how signs model reality in species-specific ways. Model making typifies all aspects of human intellectual and social life, Sebeok argued, constituting a truly astonishing evolutionary attainment, without which it would be virtually impossible for humans to carry out their daily life routines. All this suggested to him the presence of a 'modeling instinct' that is to human mental and social life what the physical instincts are

to human biological life. In effect, the main tenet of Sebeokian semiotics is that the signs made by humans to understand the world result from this instinct.

The modeling process can be simulative, whereby the form is designed to resemble its referent in some way. It can also be relational, indicating the spatial or temporal relations of referents to each other. And it can be based on cultural conventions. The form made with the index and middle finger in the shape of a 'V' to stand for 'peace' is the outcome of specific cultural events (which need not concern us here). Human modeling is unique among species because, Sebeok maintained, it was governed by four basic principles:

1. knowledge is indistinguishable from the signs used to model it (the modeling principle);
2. modeling unfolds in various ways, from simulation to culture-specific symbolic practices (the variability principle);
3. models and their referential domains are interconnected to each other in cultural contexts (the interconnectedness principle);
4. all models display the same pattern of structural properties (the structuralist principle).

The modeling principle implies that in order for something to be known and remembered, it must be assigned some signifying form. The variability principle implies that modeling varies according to the referent and to the function of a representation. The interconnectedness principle asserts that a specific form is interconnected to other forms (words to gestures, diagrams to metaphors, etc.). The structuralist principle claims that certain elemental structural properties characterize all models (paradigmaticity, syntagmaticity, etc.).

Throughout his life, Sebeok saw himself not only as an academic bee but also as an 'academic sign' that spawned further, more developed academic signs, through publication and teaching. His goal was to make semiotics a global enterprise. And in this he was largely successful. Sebeok passed away peacefully at his home in Bloomington on December 20, 2001.

Introduction

Thomas A. Sebeok (1920–2001), in company with Marcel Danesi, proposed at the very end of his long life a significant extension of the till-then standard version of semiotics owed to Charles S. Peirce (1839–1914). This new recension (Sebeok and Danesi, 2000), a theory of the systems that underlie the linking of signifiers with what they signify – or in the more clipped term of Sebeok and Danesi, 'modeling systems theory' – had two principal aims: (1) to emphasize the mental *acts* by which signifiers, or 'signs,' are tied to what they signify, and (2) to cross-cut the primary Peircean division of signs, which categorized them in terms of just the *logical* nature of what unites them with what they signify – 'index' (*actuated* by what it refers to), 'icon' (*resembles* what it refers to), and pure 'symbol' (neither actuated nor similar, hence *arbitrary*) – by newly categorizing those ties by their *complexity*. These two aims are conjoined, since in articulating and understanding signs, we may well be at least as responsive to the complexity of our associations as to their logical nature. By invoking an appeal to the mental and physical nature of those who make and receive signs (most importantly, us), Sebeok and Danesi in this way began to build a much-needed foundation for the science of 'cognitive semiotics.'

Peirce's mighty though tenebrous works (edited and published posthumously, from 1931 to 1958) had defined the modern practice of semiotics as being chiefly concerned with the logic of how signs have meaning, i.e., with how they are logically associated with their referents. A sign (e.g., a weather vane) that is perceived as being somehow actuated by its imputed referent (the local wind's direction), Peirce defined as being thereby indexical; a sign (e.g., a road sign indicating 'curve ahead'), perceived as somehow resembling its imputed referent (the upcoming curve), was for him iconic; and the default case, anything else (e.g., the word 'horse'), with a relation to its referent that is perceived only as being wholly arbitrary (the word 'horse' is neither actuated by nor in any known way physically like a horse), was thereby for him symbolic. A sign is a sign only to him or her who perceives it as such and ties it to some referent; Peirce, though, was rather incurious about the actual perceptions, as psychological processes. Though his sign-referent relations were indeed mediated or extended by a third entity called the 'interpretant,' his interpretants were just further signs, and were no less abstract. His interpretants were not creatures with earthly minds and finite brains; they could just have well been Martians or angels. So his signs were not affected by the real predispositions of minds and brains or by their ability (or inability) to juggle complex significations – as, of metaphors, for example (*that man is a pig*) – or by the mere fact that brains are physical and reside in bodies that inhabit and respond to a physical world rife with other physical things clamoring for, and often intended for, speedy interpretation. Nor, given his time and place, did Peirce accord the physiological execution or recognition of signs, as, for instance, by our neural speech mechanisms and by our vocal and auditory tracts, much serious attention, even though we are so natured and nurtured as to be capable of rapidly making and distinguishing some sounds and sequences but never others. Peirce was above all a logician, and one rather removed from the mundane claims of the corporeal, especially during the latter and reclusive half of his life that yielded most of his voluminous semiotic writings.

Sebeok and Danesi's new categorization of signs and referents, in terms of their individual and joint complexities, imposed on signs, then, a fresh rank-ordering, from simplest to most complex, ranging upward from simple signs tied to simple referents, through simple signs tied to complex referents, and then complex signs tied to simple referents, to, finally, complex signs tied to complex referents. (Somewhat different notions of 'complexity' are involved in their hierarchy.) An example at the first, or lowest, level of complexity (simplex signs/simplex referents) is the word 'cat' as tied to "a single referent or referential domain" (Sebeok and Danesi, 2000: 20) such as a particular cat or the set of all cats. Sebeok and Danesi called such a sign 'singularized.' At the next higher level (simplex/complex), we find the metaphorical, or in their term 'connective,' sign, as found in the sentence *That Louis Armstrong, he's a real cool cat*, in which 'cat' is still a simple sign (a word) but its referent is complex, being both feline and human. (To signs of this second level, and to those of the third and fourth, Sebeok and Danesi applied the term 'form,' but here, except where otherwise noted, the traditional term 'sign' will be preserved for the reader's convenience.) At the next higher level (complex/simplex), the sign is complex while its referent is simple: this Sebeok and Danesi called a 'composite' sign – for instance, the complex sign 'popular household pet that is useful for killing mice and rats' and

the (relatively) simple referent '{the set of (all) cats}.' At the fourth and highest level (complex/complex), a 'cohesive' sign provides a definition in which, for example, the same 'popular household pet' is placed in a Linnaean codification of related felines such as '{cat, tiger, lion, cheetah . . .}' (2000: 3).

Details

In their initial exposition, Sebeok and Danesi focused on symbols to the exclusion of the other two sorts of Peircean signs, indexes and icons, but clearly icons can also participate in these complexity relations. For instance a model of the dirigible Hindenburg, as standing for (and resembling) the real thing, would be a 'singularized' (simplex/simplex) sign in their scheme, and a picture of the Hindenburg erectile and spewing flames, interpreted both literally as referring to the Hindenburg and metaphorically as referring to a certain physiological event, would be a 'connective' or metaphorical (simplex/complex) sign. A Hindenburg model denoted by being placed in a Linnaean set of models of other equally doomed rigid dirigibles ({the R101, the Shenandoah, the Akron. . .}) would be a 'cohesive' or complex/complex sign, at the fourth and highest level of complexity. (That such sets are indeed subjectively defining can be seen in the fact that the set of models just named would most likely define the Hindenburg model as representing a '(rigid) dirigible'; however, placed in a different and superordinate set, including replicas of {the Titanic, the Queen Mary 2, and the Normandie}, the Hindenburg model would more likely lend itself to being defined as representing 'a large passenger ship.') Even an index such as a weather vane might be a connective or metaphorical sign if interpreted as signifying both the local wind and, say, a politician who changes direction with every passing breeze. Thus, as is seen, the new Sebeok–Danesi complexity categories cross-cut all three kinds of signs of the familiar Peircean typology. The weather vane that is tied both to a literal referent (the local wind) and a metaphorical one (a malleable politician) is, of course, at the same time both an index and a symbol, albeit a symbol for changeability (in politicians) that is based on the changeability of the index (the weather vane) with which the symbol is paired in the connective sign the two referents share. This issue returned in Sebeok and Danesi's notion of 'extension,' whereby a sign of one category becomes a sign of another (see later).

In these new complexity categories, which are therefore thoroughly cross-classifying, Sebeok and Danesi notably expanded the ways in which signs are defined, and in a way that bids fair to provide a means of heightening their potential for achieving psychological reality, if people prove responsive to their signs' complexities, as they demonstrably do to their logical or Peircean nature, as reported by psychological experiments (e.g., Paivio and Walsh, 1993; Katz *et al.*, 1994).

Plumbing more deeply into the issues they thus raised, Sebeok and Danesi proposed that signs of whichever of their four categories, joined to what they signify, can be arrived at through any (or any combination) of the three logical means fingered long ago by Peirce: by induction, deduction, or abduction – that is, by inference from example, or by deduction from logical syllogism, or by informed guesswork. Sebeok and Danesi also noted that their signs can be reclassified by still another criterion, namely, by whether the signs constitute *denotata*, *connotata*, or *annotata*: these are, respectively, the simplex sign, such as the word 'house' meaning 'dwelling'; the extended sign, such as the word 'house' meaning 'legislative assembly'; and the wholly subjective sign, the word 'house' meaning, perhaps, for an individual, the abode where he or she first set up housekeeping, (for instance, with his or her earliest consort).

Both of the categorizations just mentioned again cross-cut all four of their sign types defined by relative complexity.

Icon, Index, Symbol, and Primary, Secondary, Tertiary

A third and equally profound categorization also cross-cuts Sebeok and Danesi's basic four-way classification of signs in terms of their complexity: namely, Peirce's familiar categorization in terms of logic, which, as noted earlier, sorts signs by whether they are physically associated with the referents (indexes), or resemble their signifieds (icons), or are tied to them arbitrarily (symbols). These Peircean categories can be regarded as progressing (in the order listed) from lesser to greater complexity (though see later, for further discussion), and it is therefore not surprising that Sebeok and Danesi reintroduced Peirce's three-way categorization from a fresh angle, as part of a treatment of the ways in which signs of one Peircean type can 'extend' so as to belong to another. Such extensions come about as one product of the very means by which our signs achieve representation, the process by which we go about "transforming sensory knowing into conceptual knowing" (Sebeok and Danesi, 2000: 6) or, in plain words, our way of transforming what we sense into signs to which meaning is attached (2000: 9–10).

A 'primary' such process, in this classification, is one that produces a sign (an index), by virtue of just a primitive sensory or perceptual apprehension of

something, as when a child forms a generalized mental image from perceiving the family dog. The same child might then proceed to a more complex sign, probably an icon, via a secondary transformative process, thus achieving some idiosyncratic word for the dog in question, maybe the onomatopoeic word 'woof.' That child might then advance, via a tertiary transformation, to a more abstract hence more complex sign, a symbol, such as the local word for a domestic canine, the English 'dog(gie)' or the Portuguese 'cão.' Or, equivalently, the child may come up with the familial name 'Fido,' or whatever (Sebeok and Danesi, 2000: 10). These operations are quite explicitly put forward as mental activities, and they again connect the Sebeok–Danesi theory with cognitive matters. As such, they are, of course, testable.

We return now to primary, secondary, and tertiary transformations (in particular, to their extensions), and to an alteration in their characterizations, after pausing to sketch some of the clarifying principles that, with Sebeok and Danesi, governed their theory as a whole.

Principles

Generalizing, Sebeok and Danesi (2000: 11) advanced as a fundamental thesis the notion that all semiosis, the activity of tying signifiers to what they signify, rests on six principles:

1. The modeling principle, which holds simply that all semiotic representation is the end result of (re)modeling, that is, of the process of transforming concepts and/or percepts into signs.
2. The representational principle, which holds that knowledge (as such) is indistinguishable from how it is represented.
3. The dimensionality principle, which holds that the modeling of signs unfolds on three levels or dimensions, namely, the iconic, the indexical, and the symbolic (in Peirce's senses), of which the first two are said to be "prior developmentally and cognitively."
4. The extensionality principle, which holds that more abstract models derive from (and/or incorporate) more concrete or sense-based ones, as, for instance, when the set {cat, cheetah, tiger . . .} incorporates the simplex 'cat.'
5. The interconnectedness principle, which holds that every specific sign is interconnected with other signs – words, for instance, being interconnected with gestures, and diagrams being interconnected with metaphors.
6. The structuralist principle, which holds that all signs are characterized by the same elemental structural properties.

The elemental structural properties of the structuralist principle are also, but coincidentally, six in number. They are (1) the property whereby signs are at least minimally differentiable from each other (the paradigmatic property); (2) the property whereby a given semiotic system permits some sequences (*I drive a Mercury*) while forbidding others (**Mercury I drive a*) (this they call the 'syntagmatic' property); (3) the equivalence property, which under some circumstances permits the interchange of synonymous signs, as when the Roman numeral DCLXVI can be interchanged with the Arabic number 666 (whereby hangs a tale; see Watt (1989)); the properties of (4) synchronicity and (5) diachronicity, whereby signs have a particular shape at a certain point in time and can, over time, change that shape; and finally and most fundamentally (6), the property of significance, whereby signs can have meaning: that is, the property whereby a relation can obtain "between [a] physical signifier and [a] referent . . . to which it calls attention, namely, [its] signified" (Sebeok and Danesi, 2000: 12–13).

It is to be noted that these six structural properties are stated to be possessed by **all** signs, of whatsoever sort; naturally, the signs of more complex semiotic systems (language, for example) can possess still other properties. For example, the sign *I drive a Mercury* is more than a mere sequence of words, it is also a syntactic structure consisting of a noun phrase and a verb phrase (respectively, 'I' and 'drive a Mercury'), in which the first and second components are fitly characterized as 'subject' and 'predicate' and can be intuitively recognized as such by speakers. That superficial (subject + predicate) structure is, of course, capable of being analyzed into layers of progressively deeper armature (for instance, the predicate *drive a Mercury* resolves into the verb 'drive,' in the present continuative tense, and its object 'a Mercury'; and *a Mercury* resolves into the determiner 'a' plus the noun 'Mercury' that it modifies). Even the simple letters of the alphabet have an internal structure, 'B D E F' and so on, being analyzable as consisting of a *vexillum* or *hasta* – '|' – plus an augmentation to the right (Watt, 1992). The fact that, save in the case of 'J,' the augmentation is always to the right has a significance of its own (basically, that we write and read from left to right and so establish the basis of a letter ('|') before proceeding to the loops or whatever that differentiate one vexillary letter from another). So signs of various sorts can have underlying structures both superficial and profound that can have significance in their own right, and there are therefore 'properties,' arguably less universal than the six of Sebeok and Danesi's list, that are yet to be added to the list.

A Minor Triad: Symptom, Signal, and Name

All signs, starting with their singularized, or simplest, sign, Sebeok and Danesi subcategorized as iconic, indexical, and symbolic (the traditional Peircean division), plus the symptomatic, the signalic, and the nominal (Sebeok and Danesi, 2000: 20). The last three categories of sign characteristics are, of course, ordinarily considered to be but special cases of the classical three Peircean categories (or dimensions; see earlier), but, still, they are after all rather distinctive. Thus a 'symptom' is a special class of the index, since it is taken as a sign by virtue of its being physically caused by an interior state, most often an indisposition; and a 'name' is any arbitrary sign that both points to and identifies something ('Albert Einstein,' 'Fido,' 'newt') and is therefore, in Peircean terms, both an index and a symbol. Sebeok and Danesi defined a signal as any sign that "triggers a reaction on the part of the receiver" (2000: 22–23), which definition seems to fit all three Peircean kinds of signs, whether index, icon, or symbol, since all signs can perform this function – indeed, they **must** perform it to act as signs. Still, it is useful to distinguish at least the 'symptom' and the 'name.'

Conversions and Metasymbols

Sebeok and Danesi's firmest point of departure from abstract semiotic studies was, as remarked earlier, their postulation of the mental representations that are the ties between signs and what they signify. In fact, their discussion of this issue formed the very heart of their treatment, which is clear from their describing the act of forming such a representation as "converting information from one form into another" (Sebeok and Danesi, 2000: 33). Their introductory illustration of this process came from the life of bees, which, in their dances, with "amazing accuracy" (2000: 30), convert the details of flight to and hiveward from a food source into a communiqué of the direction of the source from the hive, its distance, and its quality. Sebeok and Danesi compared this feat to our making of nautical charts, which convert location on this globe into Cartesian coordinates in terms of longitude and latitude and into an (iconic) indication of shorelines, shoals, and like hazards (2000: 32). They also compared it to the process by which we convert Arabic numbers into Roman numeral systems – e.g., again, 666 into DCLXVI – and to the similar process by which we convert ordinary spelling into the dots and dashes of Morse code (2000: 36), as when the distress signal 'SOS' was transmitted ('. . . – . . .') from the sinking RMS Titanic. They then proceeded to the modeling of more complex connective signs (2000: 37–39), in particular those signs we are used to calling 'metaphorical.' Here, their main instance is the metaphor by which we deal with the inchoate act of understanding by transforming it into the accessible act of 'seeing,' as illustrated by the exclamation *I don't see* (= understand) *what you mean*. A further 'connective' remove from immediate accessibility is provided by an example such as *As far as I can* ***see,*** *that theory is a little blurry*, wherein, again, there is nothing concrete to be 'seen' at all. Leaps such as these Sebeok and Danesi identified as involving 'metaforms' (and by extension 'metametaforms' and so on), whereby 'understanding' has been converted into 'seeing' and more particularly into 'focusing.' What this view discloses is in fact a chaining process, infinite in principle, in which 'understanding' is conveyed by 'seeing' and 'seeing' (through a lens) is narrowed to 'focusing.' This constitutes a most intriguing approach to the treatment of metaphor and particularly to the fact that metaphors burgeon in unexpected manners and to unexpected removes, provoking the mind to follow them in a most gratifying way. This, surely, is one of the benefits (not the only one) of poetry, and one as well clarified here as in many other places during the many centuries of its treatment by literary critics. And, as Danesi (1993: 73 *et passim*), among many others, noted, this kind of metaphorical extension is also a fruitful source of linguistic innovation.

Sebeok and Danesi (2000: 40, 150–151) carried their treatment of connective semiosis a step further in their discussion of the metasymbol, such as the rose as a symbol for human love, a connection that depends on the rose's color and scent and generally pleasurable qualities, which qualities (quite apart from color and scent, unless, say, an inamorata is red and aromatic) are also those imputed to a loved one. Sebeok and Danesi concluded their section on connective semioses by opening their framework to the metonym, wherein one thing is used to refer to another, often in a *pars pro toto* way, as when we say *She's been reading Tolstoy*, whereby 'Tolstoy' stands *pars pro toto* for Count Leo's works, such as *War and peace*.

Varieties of Semiosis: Primary, Secondary, and Tertiary

Sebeok and Danesi presented a method, which they termed 'systems analysis,' for studying all varieties of semiosis, as practiced by creatures of whatever degrees of sophistication (but especially humans). To avoid confusion from the outset, it is to be noted that

in presenting this methodology they mostly assigned iconlike or imitative sign-making to their primary variety of semiosis, and indexlike or causative sign-making to their secondary variety, thus reversing the rank-ordering they followed in their earlier presentation of transformations. This apparent change of heart is presumably to be attributed to the fact that settling the issue of which is more primitive or more primary, the index or the icon, is very much an open question. Certainly from one vantage the index may seem more primitive; from another, the icon may seem more primitive, depending on whether the word 'moo' is regarded as more primitive than a wind-actuated weather vane.

At any rate, Sebeok and Danesi characterized the primary modeling system as that which "allows organisms [of whatever sort] to simulate something" (2000: 45) – that is, produce an iconic sign – in order to communicate with other organisms (mainly those of like sort). They identified two sorts of simulation, namely, the spontaneous and the imitative, which they termed the 'osmotic' and the 'mimetic,' respectively. When people reveal what they are feeling by spontaneous facial expressions the disclosure is osmotic; when they describe some sound as a 'crash' or a 'moo,' their crudely imitative emission is mimetic. ('Crudely imitative,' because colliding cars do not say *crash* and cows could not say *moo* if their lives depended on it.) Sebeok and Danesi followed their initiating discussion of the onomatopoeic imitation of heard sounds with an illuminating general treatment of the iconicity of words that audibly resemble, in some salient way, what they signify. Of course, some of these 'resemblances' are adventitious since, as Maurice Bloomfield (1895) pointed out long ago, when a number of words have formed a paradigm by sharing both a meaning and a sound (however this came about), speakers may associate this (arbitrary) shared meaning with the shared sound, and thus, in time, swell the paradigm by swerving like-sounding words into having like meanings, or even by inventing new ones of the same nature. An example is provided by the many English words in initial 'fl-' that betoken a flowing of some sort ('flow,' 'flux,' 'flood,' 'flue'), and which seem to have gravitated toward each other in such a way as to suggest that 'fl-' betokens a flowing in its own right, despite the prevalence in English of the many other non-'flowing' words, equally salient but not saliently part of a paradigm, such as 'flea,' 'floozy,' and 'flim-flam,' plus the occurrence of words also beginning with 'fl-' that betoken meanings of a different paradigm, meaning some sort of transient visual phenomenon ('flame,' 'flicker,' 'flitter,' and the like). Another example is the paradigm of words beginning with 'sn-' ('snout,' 'sniffle,' 'snort'). A seeming example of innovation into the latter paradigm is the pleasing creation of 'snorfle' (from the Coen brothers' 1994 movie, *The Hudsucker proxy*) – presumably a portmanteau of 'snort' and 'snuffle' – meaning something like 'to lap up noisily.'

Having applied their treatment of primary (or primitive) modeling systems to singularized modeling (simplex sign, simplex meaning), Sebeok and Danesi proceeded (2000: 58) to a discussion of primary composite modeling, wherein complex signs are combined to denote simplex meanings, as when sentences seem (to some) to order the order of mention of their constituents so as to convey a corresponding order of intended saliency, as perhaps in *Water, said W. C. Fields, was unfit for human consumption*, or, often, so as to reflect an order of initiative, with the actor therefore first and the acted-upon second (*Jack kicked Jill*). Sebeok and Danesi then passed on to primary cohesive modeling (complex sign, complex meaning), found especially in the nonverbal codes, such as those of courtship, that are found across species, ranging from cockroaches to humans. (Granted, though, when Grace Kelly swivels to kiss Cary Grant in the Hitchcock movie *To catch a thief* (1955), she looks supremely unroachlike.) Last, Sebeok and Danesi considered primary connective modeling (simplex sign, complex meaning), the metaphorical signs of which designate, as Sebeok and Danesi justly remarked, not denotata (direct meanings in the usual sense), but connotata (indirect meanings merely implied). In *the professor is a snake*, as they noted (2000: 71–72), clearly the speaker is not asserting that the professor is truly ophidian (has scales and fangs, crawls on his belly), but rather that he displays some of the other undesirable characteristics popularly ascribed to serpents (stealth, unwholesome appearance, an overwillingness to envenom). Finally, Sebeok and Danesi proceeded to specify some of the image schemata, or 'binary iconic features' – here, of course, they follow Lakoff and his collaborators (e.g., Lakoff and Johnson, 1980; Lakoff, 1987, 1993) – that underlie metaforms, such as those just mentioned, and which provide their "psychological source[s]" (2000: 76). For example the 'thinking = seeing' metaform taken up earlier, wherein 'see' is used to mean 'think,' Sebeok and Danesi noted must be based on the notion that 'thinking' is an 'internal seeing' of a sort. As they also noted, these more concrete embodiments of abstract actions such as 'thinking' are so much more vividly felt than their corresponding abstractions are that they probably offer a firmer basis for many feats of memory. The kind of sensory information that motivates such metaforms thus makes possible a lively mediation between the *Umwelt* (the perceived outer world)

and the *Innenwelt* (the inner world), to use von Uexküll's (1926) terms.

These points concluded Sebeok and Danesi's treatment of primary, or primitive, modeling systems, those that spring from a sensory or perceptual apprehension of a thing. They then discussed the secondary and tertiary modeling of systems, the first entailing an elementary reference to a thing in an indexical manner, the second entailing a more advanced reference to a thing, i.e., in a symbolic manner. (A tertiary, or symbolic, reference is more advanced in the obvious sense that it is derived from the cultural environment, hence is chiefly the special province of humans (2000: 82ff).) As part of this discussion, Sebeok and Danesi took up the topic of what they called 'extension' (2000: 296ff), a process whereby a sign of the primary or iconic level of simple apprehension, for example, can be raised to a higher level. Thus, the word 'crash,' which as a crude imitation of a sound is by definition basically primary, becomes altogether raised to the tertiary or symbolic level when it is extended, losing any direct reference to sound as such, so as to occur in a sentence such as *His business has crashed*. (As was noted earlier, all imitative words such as 'crash' are already partly arbitrary, hence partly symbolic; Sebeok and Danesi's point is best elucidated by considering that, when extended upward, the imitative quality of all or almost all of such words can be bled out of them. The point is a delicate one, but it may be clarified by considering some words that are highly imitative, such as 'ding-dong' and 'bang,' next to some words that are much less so, if at all, such as 'bell' and 'blast.')

Signs originating at the tertiary level, though they are already arbitrary hence symbolic, can be extended **within** the tertiary level to become symbolic in some other sense. Thus the tertiary word 'blue,' which begins by referring simply to a color, can become symbolic in some extended sense – without, of course, becoming any more arbitrary – when transferred to the phrase 'blue movie,' in which 'blue' means 'pornographic.' (The association between 'blue,' referring to the color, and 'blue,' meaning 'pornographic,' apparently originated long ago, when jailed prostitutes were dressed in blue (cheaply dyed) uniforms, which they then wore when released back onto the streets to ply their trade anew (Roppolo, 1953).)

Though Sebeok and Danesi considered only 'upward' and 'sideward' extensions (e.g., primary to tertiary and tertiary to tertiary), their analysis can easily be amplified to include 'downward' extensions as well. Thus the word 'crash,' to take an example used earlier, after it has been divested of its imitative quality by being lodged in a sentence such as *His business crashed*, can be 'reprimarized,' so to speak, regaining a little of its lost imitative character, by adding *and he had to hire a lawyer to pick up the pieces*. In any case, Sebeok and Danesi's discussion of extensionclarified a most intriguing problem, that of describing how signs originating in one Peircean paradigm can shift sideward within it or shift upward or downward into another.

Conclusion

In their summative final chapter, Sebeok and Danesi (2000: 158–189) looked back over their various schemata and, given the limitations of present knowledge about signs and signification, they invested them with fresh psychological import and made them available to empirical typological techniques. In so doing, they have redirected the emphasis of semiotic inquiry from the investigation of the logical nature of the sign–signified relationship to the study of semiosis, the **activity** through which sign becomes tied to signified. This redirection is nowhere better exemplified than in their definitions (2000: 161 ff) of semiosis as the "neurobiological capacity to produce [signs]" and of modeling as "the channeling of the semiotic activity towards . . . the representation of some referent" (i.e., the representation of something to be signified by a sign that signifies it). So modeling, as they put the matter succinctly, "reveals how the brain carries out its work of transforming sensory forms of knowing into internal forms of thinking and external forms of representation," so that "a specific external model is thus considered to be a 'cognitive trace' to the form [that] a concept assumes in the mind." Given their classificatory schemata, their exposition, and their rich set of examples, Sebeok and Danesi have provided a principled means of categorizing signs and the activities that use and extend them so as to achieve an apperception of the world we sense by means of recasting that world as the signs by which we understand it.

Not that long after the execution of his brother, Vladimir Lenin was himself banished to Siberia because of his political activities. In Imperial Russia, Lenin knew that the sequence of punishments for political offenses was first imprisonment, then banishment to Siberia, then banishment abroad, and then, execution. He was on step 2 of this sequence. He also knew that after his period in Siberia he would not cease his political activities and that the next stage would very likely be banishment outside Russia. Anticipating this possibility, he had evidently decided that his countries of choice for banishment would include Britain, and therefore it would be sensible to prepare himself, in Siberia, by learning English. Accordingly, he devised his own method. First, he tabulated and learned all the nouns. Then he went on to the verbs, the adjectives, the syntactic rules, and so on. He concluded that this systematic approach would enable him, on arrival in London, to converse with the locals. As it happened, he was amazed to discover that not only could he not converse well, he could not converse at all, and still less understand what people said! This chapter will explore factors that are relevant to the learning of a language, as well as the teaching that can promote such learning. It will review research into the nature of learning and acquisition and then go on to consider current views on the nature of language instruction. These reviews may shed light on the alternative courses of action that Lenin might have adopted.

Learning and Learners

We will consider language learning first, since it has a more fundamental role. A number of preliminaries are unavoidable here. First, there is the issue of a critical period for language, that is, a period during which acquisition is different from other learning processes. It will be assumed that there is such a critical period. Robert DeKeyser has demonstrated clear age-on-arrival effects for ultimate level of proficiency for Hungarian immigrants to the United States, that is, the younger the arrival, the higher the eventual performance. This research is far-reaching in its consequences. It implies that subsequent (second) language learning is mediated by general cognitive processes, an interpretation that has important consequences for instruction especially.

The second underlying issue concerns the concept of a focus-on-form. Michael Long has argued consistently that when learners engage in interaction, it is natural to prioritize meaning, with the result that form does not obviously come into focus. As a result, for effective learning to occur, it is necessary to *contrive* a focus-on-form, but in such a way that meaning is not compromised or distorted. A focus-on-form approach is consistent with current conceptualizations within cognitive psychology regarding the functioning of limited capacity attentional and memory systems. We cannot attend to everything, and so attention has to be directed selectively, and memory resources, especially working memory, have to be used efficiently.

The third underlying issue is over whether what is learned (the representation issue) is implicit or explicit, and indeed whether the learning process is

Not that long after the execution of his brother, Vladimir Lenin was himself banished to Siberia because of his political activities. In Imperial Russia, Lenin knew that the sequence of punishments for political offenses was first imprisonment, then banishment to Siberia, then banishment abroad, and then, execution. He was on step 2 of this sequence. He also knew that after his period in Siberia he would not cease his political activities and that the next stage would very likely be banishment outside Russia. Anticipating this possibility, he had evidently decided that his countries of choice for banishment would include Britain, and therefore it would be sensible to prepare himself, in Siberia, by learning English. Accordingly, he devised his own method. First, he tabulated and learned all the nouns. Then he went on to the verbs, the adjectives, the syntactic rules, and so on. He concluded that this systematic approach would enable him, on arrival in London, to converse with the locals. As it happened, he was amazed to discover that not only could he not converse well, he could not converse at all, and still less understand what people said! This chapter will explore factors that are relevant to the learning of a language, as well as the teaching that can promote such learning. It will review research into the nature of learning and acquisition and then go on to consider current views on the nature of language instruction. These reviews may shed light on the alternative courses of action that Lenin might have adopted.

Learning and Learners

We will consider language learning first, since it has a more fundamental role. A number of preliminaries are unavoidable here. First, there is the issue of a critical period for language, that is, a period during which acquisition is different from other learning processes. It will be assumed that there is such a critical period. Robert DeKeyser has demonstrated clear age-on-arrival effects for ultimate level of proficiency for Hungarian immigrants to the United States, that is, the younger the arrival, the higher the eventual performance. This research is far-reaching in its consequences. It implies that subsequent (second) language learning is mediated by general cognitive processes, an interpretation that has important consequences for instruction especially.

The second underlying issue concerns the concept of a focus-on-form. Michael Long has argued consistently that when learners engage in interaction, it is natural to prioritize meaning, with the result that form does not obviously come into focus. As a result, for effective learning to occur, it is necessary to *contrive* a focus-on-form, but in such a way that meaning is not compromised or distorted. A focus-on-form approach is consistent with current conceptualizations within cognitive psychology regarding the functioning of limited capacity attentional and memory systems. We cannot attend to everything, and so attention has to be directed selectively, and memory resources, especially working memory, have to be used efficiently.

The third underlying issue is over whether what is learned (the representation issue) is implicit or explicit, and indeed whether the learning process is

itself implicit or explicit (the transition issue). Allied to this is the question as to whether something that was initially explicit, e.g., a language rule or a structural pattern, can become implicit, or vice versa. The implicit-explicit distinction has largely replaced the earlier contrast between learning (explicit) and acquisition (implicit), and this realignment has been associated with a greater influence from contemporary psychology, and a strong interest in operationalizing the difference between implicit and explicit learning. Where people stand on this issue also has an important impact on different views of instruction.

Finally, by way of preliminaries, there is the question of the stages through which learners pass. It is useful to think of:

- Input processing strategies and segmentation
- Noticing
- Pattern identification, restructuring and manipulation
- Development of control
- Integration and lexicalization

Learners, of course, may be at different stages in this sequence for different parts of their developing language systems.

Each of these stages raises issues regarding the nature of second language learning. Bill VanPatten has argued that learners can benefit from being taught how to process input more effectively in order to focus on form. At the next stage, Dick Schmidt has developed the concept of noticing, arguing that before some aspect of language structure can be learned, it first has to be noticed, preferably with awareness. For Schmidt, the gateway to subsequent development is attentional focus, since it can permit deeper processing. In taking this position, Schmidt is arguing against Krashen's ideas on naturalistic learning and the acquisition-learning distinction. Clearly, though, whether noticing triggers explicit or implicit processes, the next stage in development is that the element that is noticed should become the basis for the learner identifying some sort of structural regularity in the language. This might be a new pattern, or the complexification of an existing pattern, and is the phase that accounts for development in the interlanguage system.

To perceive a structural regularity in the target language, however, does not mean that it can be used. Interlanguage development may sometimes be sudden and complete, but most accounts of second language learning assume that first insight has to be followed by a process of gradually increasing control over a new form. During this process, it is assumed that slow, effortful, and attention-demanding performance, which may also be error-prone, is progressively replaced by less conscious, easier, automatic, and fast performance. In this, the skilled control that is achieved over language performance resembles learning that occurs in other domains. Researchers have been interested in exploring the conditions that can enhance this development optimally, as well as describing the course and speed of such learning. A number of researchers, such as Nick Ellis, use general laws, for example, the power law of practice, to describe such learning.

In previous years, it was generally thought that the development of a high degree of automatization and control would have been the end-point of the learning process. In the last twenty years or so, linked perhaps with the development of corpus linguistics, there has been a greater realization of the importance of formulaic sequences and idiomatic language. That is, rather than prefabricated language being a minor part of the psycholinguistic abilities of the speaker, they are now seen as pervasive and vital for real-time communication. It is assumed that highly competent language users rely on formulaic language to ease the processing or computational burden during ongoing language production, and to sound native-like.

Having explored these preliminaries at a more explanatory level, there are a number of theoretical accounts relevant to the nature of second language development. Obviously the first to consider here is Universal Grammar (UG). Researchers influenced by this approach take a range of different positions, for example, full transfer/full access, vs. for example, residual access through previous parameter settings. Basically, all approaches assume the importance for second language learning of the continued existence of a Universal Grammar but differ over the impact that L1 learning has on this development. Lydia White proposed that it would be more appropriate to consider the role of UG in second language development as constraining the problem space, and requiring that L2 grammars be consistent with it, rather than expecting the L2 grammar to follow a deterministic path. In any case, in terms of relevance for instruction, there is the issue that UG researchers, necessarily, investigate features of language that are thought to be revealing about the operation of UG. In the main, these features, for example, the 'empty category principle,' the 'overt pronoun constraint,' do not follow the priorities of others, for example, language teachers. Second language research may therefore be more revealing for Universal Grammar than Universal Grammar is for language teaching.

An interesting contrast to UG that has emerged in recent years is William O'Grady's 'general nativism.' In this, there is acceptance, as with UG (which O'Grady terms 'grammatical nativism'), that human

beings are 'wired' to perform learning tasks in a certain way, but O'Grady proposes that this nativist capacity is general in nature, rather than a module specialized for language. He suggests that the more general propensities (a) to operate on pairs of elements, and (b) to combine functors with their arguments at the first opportunity, are sufficient to account for the nature of language development and the structures that emerge. It is too early to evaluate this approach as yet, but it is interesting that there are slight affinities between it and that of another theorist, Manfred Pienemann and 'processability theory.' Drawing upon lexical functional grammar and Levelt's processing model, Pienemann takes as fundamental a performance-based incremental approach to language generation. He offers a different set of processing procedures and routines to O'Grady, for example, lemma access, the category procedure, etc., but he, too, then makes predictions about sequences in second language development. So in either case, the nature of the grammar that results, is seen as the consequence of processing procedures.

In contrast, there have also been proposals in recent years to account for second language development through connectionist architectures. These are networks of associations, involving several layers to connect inputs and outputs, i.e., containing hidden layers that serve as general-purpose learning devices. They are implemented through computer software, and this software can 'learn' and be tested. For example, it could take the input of a simple verb form in English and the output would be a past tense form. Such networks can be trained to produce highly accurate past tense outputs, for example, including characteristic mistakes that second language learners make. There is nothing specifically linguistic about the networks, so they are used to support the claim that specialist modules are not required for languages to be learned. The best known example of a connectionist network applied to second language learning is the competition model. This uses cues such as animacy and word order to predict how well learners with different L1/L2 combinations will learn how to assign subject and object roles in sentences.

The approaches to learning covered so far have focused on individual mental structures and processes. But other approaches have been more concerned to situate learning within a social context, and to explore the potential that interaction provides to give learners useful data. One example of this is Long's interaction hypothesis. Assuming the inadequacy of input alone (i.e., positive evidence), Long focuses on the provision of negative evidence, i.e., evidence that a mistake has been made. He proposes that such evidence can be obtained within natural interaction. In particular, he proposes that particular sorts of interactive encounter, i.e., those in which there is negotiation of meaning, leading to feedback moves such as confirmation checks, comprehension checks, clarification requests, and especially interlocutor recastings of the L1 speaker's utterance, provide timely and personalized negative evidence without compromising the (vital) naturalness of communication. This approach is located within Long's proposals for the importance of a focus-on-form, since form is brought into focus incidentally through these conversational devices, enabling learners to attend to it and perhaps, at a later stage, incorporate the effects of such feedback into their interlanguage. There have been questions as to whether there is immediate uptake of recasts that are offered, but Cathy Doughty argued that immediate uptake may not be the most effective way to detect the influence of recasts on subsequent development.

Also concerned with interaction, but from a radically different perspective is sociocultural theory (SCT). Drawing on Vygotskyan theory, the emphasis here is on the collaborative, unpredictable meanings that will develop through conversation, with each partner making contributions that can be taken up and extended by their interlocutor. Jim Lantolf argued that this is a fertile ground for second language development, and sociocultural theorists claim that tasks that generate lower negotiation for meaning indices (e.g., a discussion task) may provide other more useful scaffolding for language development, since they push learners to build meanings collaboratively, and to engage in more extended turns. Indeed, developing the notion of interaction, Merrill Swain has proposed that output is vital for second language learning since it pushes learners to do things like notice gaps in their interlanguage; to explore and test out hypotheses; and to attain a metalinguistic level of processing.

We turn now to consideration of learner characteristics and differences. The remainder of this section on learning will cover language learning aptitude, motivation, language learning strategies, and personality. Earlier conceptions of foreign language aptitude, strongly associated with J. B. Carroll, proposed that there is a specific talent for language learning, consisting of four components; phonemic coding ability (the capacity to analyze sound so that it can be better retained); grammatical sensitivity (the ability to identify the functions that words fulfill in sentences); inductive language learning ability (the ability to take a sample of a language and extrapolate to further language); and associative memory (the capacity to make links between items in memory). This view of aptitude, underpinning older aptitude

test batteries (for example, the Modern Languages Aptitude Test), was reasonably successful, since these batteries led to correlations of around 0.40 between aptitude and achievement test scores. It has not, however, had great recent influence, partly because it has been argued that this conception of aptitude is irredeemably linked to instruction, indeed particular forms of instruction, such as audiolingualism, rather than to informal and acquisition-rich contexts.

More recently, however, a reassessment of aptitude has taken place. A new aptitude battery has been developed, CANAL-F. The battery incorporates cumulative, thematized learning within the sequence of subtests. Aptitude has also been reconceptualized and linked with second language acquisition processes, following the stages outlined above (noticing, pattern identification, etc.), and this sequence can also be related to the constructs that are said to underlie CANAL-F, such as selective encoding (noticing) and selective transfer (inductive language learning ability and pattern restructuring). Complementing this, there have been studies that have linked aptitude information to acquisitional contexts. These studies have shown that aptitude generates correlations with informal and implicit learning conditions as well as explicit ones. Indeed, reviews of the available evidence demonstrate that predictive relationships emerge in both informal and formal settings.

Motivation has seen an even greater diversification of research. This area has been dominated by the work of Robert Gardner, whose analysis of motivation in terms of integrative and instrumental orientations has been fundamental. He has continued to publish and to extend his model of second language learning. However, some earlier reviews of his work that called for a widening of the research agenda have led to different perspectives. There have been proposals for slightly different conceptualizations of motivational orientation, but essentially still within the Gardner framework (for example, proposals for knowledge, travel and friendship orientations, and suggestions that a world 'modernity' orientation is relevant).

There has also been a widening of the theoretical framework for motivation, with greater connections with mainstream psychology. For example, one perspective emphasizes linguistic self-confidence, which links with willingness to communicate research (WTC). This explores the reasons that underlie a learner's readiness to actually engage in communication. There have also been some studies on motivational attributions, and these indicate the richness of attributional thinking on the part of language learners and the impact such thinking can have on the maintenance of motivational strength. Such studies also indicate how qualitative methodologies can be applied to the motivational arena.

Perhaps the greatest change in motivation research concerns the temporal dimension. Many have argued that motivation needed to be related more clearly to the classroom, and conceptualized dynamically, rather than in terms of static, unchangeable orientations. Zoltan Dornyei, for example, uses action control theory as a way of achieving this. He argues that one needs to explore influences before a task is done (for example, motivational orientations), different influences on motivational levels while a task is done (stimulating activities), and also the post-actional stage, where learners reflect after learning on the degree of success they have achieved, and its likely explanations, such as a personal lack of effort. Such posttask refection may lead learners to make attributions that will influence future motivational levels. Interestingly, Gardner's latest research also explores the issue of the malleability of motivation, and how some aspects of the Gardner model, such as integrative orientations, do not seem malleable, while other areas, such as attitudes towards the teacher, are.

Learning strategies research has continued to be researched intensively. Some early problems with this area continue to cause difficulty. One of these is the categorization of learning strategies, and area about which Ellis suggested: "definitions of learning strategies have tended to be *ad hoc* and atheoretical." In response to this, Zoltan Dornyei and Peter Skehan suggested that one should operate with four main classes of strategy:

- Cognitive strategies
- Metacognitive strategies
- Social strategies
- Affective strategies.

They also draw attention to the way that within mainstream psychology, there has been a movement away from learning strategies and toward the term 'self-regulated learning,' which more generally captures the learners' conscious and proactive contribution to enhancing their own learning process. Interestingly, though, there has been recent evidence based on a confirmatory factor analysis in an attempt to distinguish between the various models that classify learning strategies, and this suggests that Rebecca Oxford's six-factor model (the above four, plus a separation of cognitive into cognitive and memory, and the addition of compensatory) best satisfied the data.

Perhaps the one other learner difference area where there has been interesting progress has been that of personality. Some researchers have tended to dismiss personality as the source of empirically-verifiable

correlations with language learning achievement. However, if one focuses on extroversion, it appears that applied linguists tend to have done two things (a) they have not been conversant with current theories of personality, or of associated standardized forms of personality assessment, and (b) they have tended to focus on possible relationships between personality variables and learning. When personality assessment is carried out using contemporary and validated personality inventories, results are clearly more stable. In addition, consistent correlations emerge between such extroversion–introversion measurements and foreign language performance – not with learning but with, for example, tests of speaking.

Teaching

Some twenty-five years ago, when second language acquisition research first began to have an impact, the value of instruction itself came under question, since direct evidence of its beneficial effects was slender, and it was proposed that exposure to language (and incidental learning) was sufficient for interlanguage development to occur. An important review article by Michael Long, "Does second language instruction make a difference?" responded to these issues and evaluated the available research on instructional effectiveness. Long's work was a meta-analysis – he evaluated, reanalyzed, and synthesized a wide range of studies and argued that the balance of evidence suggests that instruction does make a difference, and is associated with faster learning, and higher ultimate attainment. More recently, a major updated and extended meta-analysis has been published that demonstrates instruction does have an appreciable effect on performance; that explicit instruction produced larger gains than an implicit approach, which was, in turn, significantly greater than for control group conditions; and that instruction is durable in its effects.

What John Norris and Lourdes Ortega, in this updated meta-analysis, did not set out to do is provide a detailed justification of how instruction works, or, what specific aspects of instruction generate the differences that are found. Consequently, it is not easy to point to evidence of optimal learning environments – we simply know that having instruction compared to not having instruction is a good thing. How this lack of a fine-grained understanding of the effects of specific instructional types will be resolved is not clear. One approach is to continue to use research designs that do explore methodological comparisons that would be recognizable by teachers. Alternatively, the question may need to be posed differently. As Cathy Doughty recommends: "Rather than at the level of 'method,' the operationalization of instructional treatments is now considered best analyzed psycholinguistically in terms of input-processing enhancements that facilitate L2 learners' extracting forms and mapping them to meaning and function." She discusses a range of techniques that might achieve this, examining them in terms of degree of obtrusiveness, and also relating them to the functioning of limited capacity attentional functioning.

The preceding discussion means that explorations of language teaching options cannot be conducted simply in relation to evidence. But of course teachers need to act, and any broader research findings and theories about learning are going to be only one of the influences on such actions. We will next consider the major issues that motivate debates about teaching. Most fundamental of all, perhaps, are the topics of syllabus and methodology. The former concerns what is taught, and is traditionally approached in terms of the units of teaching, as well as their sequencing. The latter is concerned with how whatever is taught is taught. As we shall see, there have been changes with respect to each of these, although it is a moot point as to whether these changes are more characteristic of the 'chattering classes' of language teaching professionals rather than what happens in most actual classrooms.

Until relatively recently – the early 1970s – there seemed relatively little controversy in syllabus or methodology. The units of syllabus were seen to be language forms, and their sequencing was subject to reasonable consensus. True, the criteria that were used to establish syllabus ordering were not entirely convincing (for example, buildability, frequency), but there was considerable agreement about a high proportion of the ordering that was characteristic for the teaching of English, at least. This consensus was challenged during the 1970s and 1980s, and alternative proposals were put forward, with alternative units, such as functions and notions and lexical elements, and alternative classroom activities such as tasks and procedural syllabuses. Most radical of all, perhaps, was Candlin's proposals for retrospective syllabuses, where the syllabus that is taught is the result of negotiation between the teacher and learners, building on the distinction between the plan for teaching and the classroom reality of what actually happens, which are not going to be the same thing, Chris Candlin has suggested that one can only really say what a syllabus has been *after* a course has taken place. There were also vigorous attempts to develop specific purpose syllabuses based upon the analysis of learner needs.

Interesting issues have also been raised about the feasibility and limitations of planning courses, and

whether it is even worthwhile to use course books. There seemed to be strong moves to use meaning-units as the basis for teaching, and to bring the learner more centrally into decision making. But what is interesting is how this debate has lost vitality. Now there is much less debate on these issues, and, paradoxically, the solution has been something of a consensus to use forms of what are called 'multi-syllabuses,' where the early pages of a course book or syllabus document will contain a table indicating how structural units, functional units, context, themes and tasks are meant to exist in harmony, so that the syllabus can claim to comprise all the potential syllabuses in one. Even so, it would appear that some of the strands in a multisyllabus are more equal than others, and it is no surprise that the most dominant of these is the structural core.

There have also been discussions regarding what should be done within classrooms, and what methodologies are better. Significant reviews are available of the major contrasting methodologies, such as grammar translation, audiolingualism, functional-notional, and communicative approaches. Grammar-translation emphasizes written language and the use of rules (and exceptions) to construct sentences in a deductive manner. Grammar is preeminent and item-based vocabulary learning is extensive. Audiolingualism, in contrast, emphasizes the spoken language and teaches this inductively through stimulus-response-influenced pattern practice. Functional–notional and communicative approaches share a much greater emphasis on meaning and the use of (more) authentic materials. Functional–notional approaches use itemized meaning-units as a syllabus basis and are usually concerned with language use and contextualized teaching. Even so, there is the possibility that functional–notional approaches, although using meaning units, can be associated with fairly traditional practice-oriented methodologies.

Functional–notional approaches were really the foundation for the development of a communicative approach to language teaching, which is now regarded as the orthodoxy in many parts of the world. Communicative approaches come in two strengths: weak and strong. The weak form is compatible with multisyllabuses and gives communicative activities an important role, since it is assumed that learners will need to work on the development of communicative competence, and that they will not be able to do this without engaging in realistic communication of individual meanings. This goes well beyond the production phase of the three Ps, and requires authenticity of language use and genuine interaction. However, the weak form can be associated with optimism that teaching materials can blend structure, function, and communicative activity to promote balanced and integrated progress. The strong form of communicative teaching, now associated with task-based approaches, regards task itself as the primary unit and then sees language as following the demands of the task, so that the role of the teacher is to respond to whatever language the task generates as important. Jane Willis described a methodology for approaching instruction in this way, in which a language focus is the last phase in teaching, after some new language has been made salient by the need to do a task.

Of course, these are not the only methodologies that have been used, and there are other 'fringe' approaches. There are also, for example, total physical response, the silent way, suggestopedia, and community language learning, although it is interesting to note that while each of these has its devotees, it can be argued that they are becoming even less central (cf. the change in the amount of coverage in the first and third editions of Harmer's *The practice of communicative language teaching*).

The debates over methodology have been intense. In an attempt to make progress in these debates, in which distinctions between syllabus and methodology were not always clear, it has been proposed that it is fruitful to look at these issues in terms of approach (underlying theory), design (syllabus considerations), and procedure (methodology) and what goes on in the classroom, in order to characterize a broader concept of 'method.' In an ideal world, an approach to language teaching should balance all these things, but in practice, one of the three might dominate, somewhat at the expense of the others. Hence, with audiolingualism, the focus is on procedure, as well perhaps as approach, but there is much less to motivate design. In contrast, one could argue that functional-notional approaches emphasized design, but with less emphasis on approach and procedure.

It is interesting now to reflect on these debates and the intensity they used to provoke. Two issues stand out. First, prevailing practice would generally be seen as a communicative approach to language teaching, or at least this is what would be said, even if what happens in any particular classroom might not indeed be communicative language teaching. The approach has become the general orthodoxy. Second, and probably more important, we have seen the emergence of the course book series. We are now in a position where the production of course book materials is big business and associated with the commitment of very considerable resources. These resources are directed at the preparation of the course book proper, the extensive piloting of material, the development

of a wide range of supplementary and ancillary materials (including websites), even the development of associated tests. One consequence of these developments is that the role of the teacher is changed. There is less reason for teachers to devise their own materials and it is much more possible simply to 'teach the book' as the course book's ubiquitous multisyllabus is followed.

An interesting way of exploring changes in language teaching is a comparison between two editions of the same book, Jeremy Harmer's *The practice of English language teaching*. In addition to a great deal of common ground, there are some interesting changes. First, there is something of a retreat from grander ideas on syllabus and methodology, to a greater concern for techniques at a more micro level, and issues connected with classroom management. Interestingly, there is more emphasis on how to handle mistakes and how to provide feedback. Second, there is greater coverage of language itself, and of how it may now be studied through corpus analysis so that more realistic language is used. Third, there is a greater concern with course books. Coverage is provided about course book selection and how to work with a course book, changes that reflect the point made earlier regarding the greater domination of course book series presently. Finally, there is very significantly increased coverage of the role of technology in language learning, with complete chapters devoted to teaching using video, and educational technology. This last development is undoubtedly going to grow enormously in importance. There are now increasing numbers of books about the use of computers and the internet in language teaching, and leading journals such as *English Language Teaching Journal* contain regular sections detailing useful Web resources.

Language teaching, happily, still has some active areas of disagreement and debate. There are interesting proposals regarding process syllabuses, where the role of the learner in negotiating what will happen in the classroom is recognized and fostered, even to the extent of allowing learners to influence the nature of assessment. This work nicely complements applications of sociocultural theory to second language acquisition, which also regards the joint construction of meanings as fundamental (although in this case more because it facilitates acquisition itself). Process syllabus proponents are perhaps more interested in the rights of learners to influence their instruction as well as the broader societal benefits that follow from learners who learn how take personal responsibility in this way.

A second area for lively exchange concerns the role of tasks in language teaching methodology. Two sub-questions are relevant from this debate. First, there is the issue of how predictable tasks are in terms of the effects of task types and task implementation, for example, pretask planning, on the language that is produced. One response is to doubt any predictability because learners will negotiate their own interpretations in ways that reflect their own interests and desires, whereas another is to research these factors in the hope of providing evidence to assist teacher decision-making. Second, there is the issue that tasks have been attacked because it is proposed that what should really be the focus for teaching is grammar. In this view, tasks might be permissible as a form of language use after more conventional grammar teaching has taken place. It has been suggested that they should not used as the unit of language teaching, or even regarded as a means to enable interlanguage to change and develop. In contrast, others argue that tasks provide a way for acquisition processes to be brought into the classroom and become the basis for learner-driven development.

A final area of debate within methodology concerns the issue of appropriateness. There have been general debates about the connections between language teaching – especially English language teaching – and imperialism. The argument is that the teaching of English is not a neutral activity, but contributes to the perpetuation of existing international power structures, and implicitly the downgrading of local cultures and power. At a much more specific level, Adrian Holliday has argued that there has been insufficient attention paid to local needs and to the different conditions that operate in many language teaching contexts, and that another form of imperialism is the way methodologies devised in one set of circumstances are assumed to be relevant for wholly different context. At the broadest level, he contrasts two contexts and the imbalance between them. The first concerns approaches to language teaching developed for favorable circumstances (for example, Britain, Australasia, and North America, which he refers to, using the relevant initials, as BANA), a context in which individuals often pay fees for their instruction, are studying voluntarily, and in relatively small groups with good resources. In contrast, the second context, referred to as TESEP (*Te*rtiary, *Se*condary, *P*rimary) relates to state school education in the rest of the world, where there are usually large classes, with less favorable resourcing, different home-school relations, and learners who have no choice but to be in a classroom. They are also likely to be heading for a testing system that is less communicative in nature. Methodological options appropriate in the former context do not generalize easily to the latter, so

more attention needs to be paid to local cultures, realism about local resourcing, and local educational traditions.

Conclusion

As the first section of this chapter indicated, the field of second language acquisition research has made a range of interesting contributions to our understanding of how languages are learned. There are alternative accounts available and regular research output. It can even be argued that the two subfields of acquisition/learning processes and learner differences are coming together for the first time, to the mutual benefit of each. We have also seen that language teaching is an area with considerable vitality. Teaching is still strongly influenced by language description, but the consensus communicative approach has meant that a range of activities focusing on meaning are also central, and that the quality of materials available (if not always their accessibility) has improved dramatically.

As a final point, it is worth making the observation that although the two areas of learning and teaching might reasonably be expected to have strong relationships with one another, in practice, they do not. Learning/acquisition tends to have a research emphasis, and while it does have relevance for teaching, this requires some extrapolation. Teaching, in contrast, while not without interesting research work, nonetheless emphasizes other criteria in establishing and justifying its procedures. It would be desirable to see this separation reduce in the future, for the benefit of both.

Second Language Acquisition: Phonology

J Archibald, The University of Calgary, Calgary, AB, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article provides an overview of work on second language (L2) phonology that has been undertaken within a generative framework. The discussion first addresses the acquisition of segments, then the acquisition of syllable structure and of higher level prosodic phenomena. A somewhat selective view of the field is presented, but an extensive bibliography points to additional analyses for those who want to read further. In much of the discussion here, the focus is on the situation that arises when a second language learner is attempting to acquire a structure that is absent from the first language. For an overview of broader issues in second language phonology, see Archibald (1998) or Major (2001).

What Is Acquired?

The first thing to consider in looking at the acquisition of phonology in a second language is the question of what exactly is being acquired. Second language learners must acquire features, segments, moras, syllables, and feet. A theory of phonological knowledge must be adopted; the model in **Figure 1** indicates some of the areas that will be examined in the following sections. Let us begin by looking at the acquisition of L2 features.

Figure 1 Phonological structure.

Phonological Features

Brown (2000) argued that if featural representations are lacking from the first language (L1), they will be unacquirable in the L2. She looked at the acquisition of English /l/ and /r/ by speakers of Japanese and Mandarin Chinese (neither language contrasts /l/ and /r/ phonemically). The Japanese situation is diagrammed in **Figure 2**, where SV represents 'sonorant voice.' In Japanese, [l] and [ɾ] are allophones of a single phoneme. This phoneme may appear only in a simple onset in Japanese. Mandarin Chinese also lacks the contrast (and hence the structure is the same as shown in **Figure 2**). If the segment is taken to be the level of explanation, then we might predict that both Mandarin and Japanese speakers should be unable acoustically to discriminate /l/ from /r/ (given their L1 feature geometries). In general, however, Japanese speakers are unable to discriminate /l/ from /r/, both acoustically and phonologically (in lexical choice tasks), whereas Chinese speakers discriminate the contrast in both tasks. The graph in **Figure 3** shows the overall performance of participants in an auditory discrimination task designed to assess this

Figure 2 Feature geometry of liquids (SV, sonorant voice).

Second Language Acquisition of Phonology, Morphology, and Syntax

Introduction

Four questions have dominated recent research in second language (L2) acquisition: (i) What role does a speaker's first language (L1) play? (ii) Does L2 acquisition display developmental patterns that are similar across learners? (iii) Is an innately determined human language faculty involved? (iv) Why is knowledge of an L2 sometimes underdetermined by the input? This article reviews some of the empirical findings bearing on these questions in the domains of L2 phonology, morphology and syntax, and considers how answers might contribute to the construction of a theory of L2 acquisition.

L2 Acquisition of Phonology

Casual observation tells us that most speakers of an L2, where acquisition has occurred beyond childhood, have foreign accents. Is this the consequence of the pervasive influence of a speaker's L1? With some properties of L2 phonology there is early, but temporary, L1 influence, with others L1 influence is persistent, and with yet other properties the influence comes from universal principles of phonological organization.

Broselow (1983, 1988) offers a clear case of L1 influence. Native speakers of Egyptian and Iraqi Arabic, in their production of syllable-initial English consonant clusters, may insert an epenthetic vowel; i.e., a vowel that creates an extra syllable. Interestingly, Egyptian Arabic speakers insert it in a different position from Iraqi Arabic speakers (Table 1) as a result of their L1 Arabic syllable structure.

Table 1 Insertion of an epenthetic vowel by speakers of Arabic (based on Broselow, 1983, 1988)

English target form	*Egyptian*	*Iraqi*
floor	filoor	lfloor
plastic	bilastic	lblastic
children	chilidren	childiren
translate	tiransilate	itranislate

The maximal allowable syllable in Arabic is C(onsonant)V(owel)C(onsonant) (with some exceptions, irrelevant to the point here). When morphosyntactic operations in Arabic are in danger of producing consonant clusters, an epenthetic vowel is inserted. Compare (1) and (2) cited by Broselow.

(1) Egyptian katab + l + u → katablu
wrote-he to-him
Iraqi kitab + l + a → kitabla
wrote-he to-him
'He wrote to him'

(2) Egyptian katab + t + l + u → *katabtlu → katabtilu
wrote I to-him
Iraqi kitab + t + l + a → *kitabtla → kitabitla
wrote I to-him
'I wrote to him'

In (1), morphosyntactic operations combining the verb and affixes generate strings that do not violate Arabic syllable structure: *ka-tab-lu, ki-tab-la*. However, in (2), strings are generated with a non-syllabified consonant /t/: *ka-tab-t-lu, ki-tab-t-la*. Because adjunction either to the preceding or following syllable would violate Arabic syllable structure, an epenthetic vowel is inserted. But it gives rise to different syllabification in the two varieties. The Arabic speakers appear to transfer this L1 constraint into their L2 phonological representations for English.

L1 influence can also be found in the representation of segments. An interesting case of this is known as differential substitution (Weinberger, 1996: 269), where an L2 segment does not exist in the learner's L1 and the learner substitutes an L1 segment for it. But the substituting segment varies depending on the L1 in question. None of Russian, French, or Japanese have the English phonemes /θ/ or /ð/ found in the words *think* and *this*. Russian speakers substitute /t/ and /d/ for these segments, producing *tink/dis*. Speakers of French and Japanese, however, substitute /s/ and /z/, producing *sink/zis*. All of /t-d-s-z/ contrast phonemically in Russian, French, and Japanese. This is not, then, a case of simple surface substitution of one segment for another, nor random substitution of /θ-ð/ by segments in the same articulatory area. What could give rise to the observed behavior?

Weinberger suggests it is a combination of a universal property of phonological representation in human language, together with language-specific differences in implementation of this universal. The universal is the underspecification of features in the underlying representations of phonemes. Features that are entirely predictable are absent from the underlying representation of a phoneme and are filled in during the course of deriving a sentence by redundancy rules, e.g., in the five-vowel system /i, e, a, o, u/, if /i/ and /u/ are high vowels and their underlying representation is specified as [+high], the others need not be specified [−high] since this is entirely predictable. Language-specific differences arise where the inventory of phonemes in each language differs in which features are specified in underlying representations and which features are not.

Weinberger claims that the underlying representations of /s-z/ and /t-d/ in Japanese are all specified as [−sonorant] (distinguishing them from vowels, glides, liquids, and nasals), and for [+/−voice], but differ in that /t-d/ are specified [−continuant], while /s-z/ are not; the value [+continuant] is supplied for /s-z/ by a redundancy rule during the course of the derivation. In Russian, his claim is that the underlying representations for /s-z/ are specified [+continuant] while /t-d/ are not.

When speakers of Japanese and Russian encounter /θ-ð/ in an L2, they cannot initially represent this contrast (because it does not exist in their L1 phonology). Instead, they assimilate these segments to the closest minimally specified phonemes with matching features in their underlying representations in the L1: ones specified only as [−sonorant] and [+/−voice]. In Japanese the matching phonemes with the fewest features are /s-z/, but in Russian they are /t-d/. Thus differential substitution results from the interaction between a proposed universal of phonological representation (feature underspecification), a universal of L2 development (assimilation of a new segment to a minimally specified segment that matches in features in the L1), an L1-specific difference in the implementation of feature underspecification, and a phonemic contrast in the L2 that is new to the learners in question.

Is L1 influence temporary or persistent? The substitution of /s/ for /θ/ discussed by Weinberger is known to be a persistent feature of Japanese speakers. In Japanese, Mandarin Chinese, and Korean certain phonemic contrasts are not present: /s-θ/, /l-r/, /f-v/ and /p-f/. Brown (2000) investigated how speakers of these L1s treat the contrasts in L2 English. All three languages have the phonemes /s-p/, yet they lack /θ-f-v/. Furthermore, on Brown's analysis,

Mandarin Chinese and Korean have the phoneme /l/ but lack /r/, whereas Japanese has a flapped phoneme /ɾ/, which is traditionally equated with English /r/ but lacks the phoneme /l/ (although one of the allophonic realizations of /ɾ/ is an [l]-like sound).

In an auditory discrimination task participants heard two pairs of invented one-syllable words. In one pair the same phoneme occurred in syllable-initial position, while in the other there was a contrast, for example:

ra-la	ra-ra
fa-fa	va-fa

Informants were required to indicate, for each stimulus, which of the pairs was different. The participants were university students in Japan with 8 to 10 years of instruction in English, probably of high intermediate to advanced proficiency (n = 15 with L1 Japanese, 15 with L1 Mandarin Chinese, 11 with L1 Korean). Ten native speakers of English acted as controls. Results revealed that all groups, nonnative and native, correctly distinguished /p-f/ and /f-v/ on over 90% of items. However, the three nonnative groups' performance dropped below 80% accuracy with /s-θ/, whereas the natives performed at over 90% correct. This is a statistically significant difference. In the /l-r/ contrast, the Japanese and Korean speakers' (below 70%) were significantly less accurate than those of the Chinese and the native speakers (around 90%). There was no difference between the Chinese and the natives in this case.

These are surprising results. None of the tested contrasts exist in the informants' L1s. The /p-f/ and /f-v/ contrasts pose no difficulties for acquisition for any of the learners: /f/ and /v/ are acquirable, it seems, yet all learners had ongoing problems distinguishing /s-θ/, and only the Mandarin Chinese speakers acquired the /l-r/ contrast.

What could explain this selective influence of the L1 on the acquisition of new phonemes in an L2? Brown argues that the human language faculty in its initial state at birth provides a set of distinctive phonological features like [voice], [aspiration], [continuant], [coronal] etc. which would allow the child potentially to represent any phonemic contrast found in human language. When the child is exposed to a particular language or languages, only a subset of this universal inventory is required to establish a phonological representation. Unused features cease to be available to the learner at some point in development. When a learner comes to acquire an L2 later, only the range of features selected in L1 acquisition can be used for representing the phonology of the L2. New phonemes are acquirable providing that their feature composition involves features present in the L1, even if the phonemes are not present in the L2. To illustrate, Brown claims that the phonemic inventory of Mandarin Chinese includes the feature [coronal], which is required to distinguish alveolar /s/ from retroflex /ʂ/. This feature is also crucial for distinguishing /l/ and /r/ in English (on Brown's analysis). So when Mandarin Chinese speakers encounter English, they are able to set up a contrast between /l/ and /r/ involving the feature [coronal], even though /r/ is not a phoneme in Mandarin. By contrast, Japanese and Korean do not have the feature [coronal]. The /l-r/ contrast therefore remains persistently problematic for them. As for the /f-v/ contrast, it involves the features [continuant], [labial], [voice]. Although neither of these phonemes is present in Japanese, Chinese or Korean, the relevant features are present. Hence, /f-v/ poses no difficulty in L2 acquisition. Finally, none of Japanese, Chinese and Korean has the feature [distributed] that, according to Brown, distinguishes /θ/ from /f/ and /s/ in English. Hence, none of the groups is able to establish a phonological representation for /θ/.

A follow-up study by Brown comparing two Japanese native groups with L2 English (low proficiency vs. high proficiency) suggests that contrasts that are different between the L1 and the L2 are initially not represented, with L2 speakers assimilating new phonemes to existing L1 phonemic categories. If, however, features required to make an L2 contrast are present in the L1, restructuring occurs with continued exposure to L2 input.

In summary, L2 syllabic structure is initially determined by syllabic structure in the L1. Segments that are not phonemes in the L1 are initially assigned to phonemes with minimally matching sets of features. With continued experience of the L2 speakers restructure their phonological system and new phonemes are acquirable, but only if the L1 system has encoded the distinctive features required for establishing such new phonemes.

L2 Acquisition of Inflectional Morphology

Inflectional morphemes are the surface manifestation of features that are represented underlyingly in functional categories such as Inflection, Determiner, and Complementizer (Table 2).

Empirical studies have found quite similar developmental patterns in the L2 acquisition of inflectional morphology, with apparently little L1 influence. Dulay and Burt (1973, 1974) and Bailey, Madden, and Krashen (1974), using oral data, found that child and adult native speakers of Spanish, Cantonese, and other languages supplied some morphemes more frequently than others. Dulay and Burt (1974)

Table 2 Some English inflectional morphemes and the Realization of their underlying features

Inflectional morpheme	*Realization of underlying features*
Copula and auxiliary *be*	Tense, subject-verb agreement
-ing	Progressive aspect
Regular past (walk-*ed*), irregular past (*ran*)	Tense
Plural (dog-*s*)	Number]

compared Spanish and Cantonese child learners (Figure 1). Although the Spanish speakers supplied more morphemes in absolute terms than the Cantonese speakers, the relative ratio of suppliance between different morphemes was highly similar. This pattern of suppliance in oral production has been repeated in many other studies of L2 learners of English.

How can such non-L1-influenced patterns of behavior be explained? Dulay and Burt and Bailey, Madden, and Krashen assumed that frequency of suppliance reflected order of acquisition. That is, that progressive *-ing* is acquired earlier in L2 English than past tense, and copula *be* before the marking of subject-verb agreement by third-person singular *-s*. However, a recent interpretation postulates a separation between the development of syntactic knowledge and the development of inflectional morphology. Syntactic knowledge is more developed than the use of inflectional morphology would suggest. For example, Ionin and Wexler (2002) found that a group of Russian-speaking child learners of L2 English supplied past tense forms in obligatory past tense contexts 42% of the time, yet there were no errors of misuse of the past tense forms; and whereas third-person *-s* was only supplied in 22% of required cases, it was misused in just 5% of cases. Speakers appear to know the range of meanings of inflectional morphemes even if they fail to produce them in every context in which they are required. If this view is correct, then the syntactic properties underlying the distribution of inflectional morphemes in Dulay and Burt's (1974) study have been acquired. The reason why some forms are supplied more frequently than others must then be the result of something other than lack of acquisition of the underlying syntactic property.

The two views just described correspond to two different lines of theoretical enquiry in modern L2 research. One is known as Minimal Trees (MT) (Vainikka and Young-Scholten, 1994, 1996). This proposes that L2 learners' initial interlanguage grammars (ILGs) (i.e., their mental L2 grammars) consist only of projections (phrases) built from lexical heads

Figure 1 Acquisition of eleven morphemes by Spanish-speaking and Cantonese-speaking children in L2 English (Dulay and Burt, 1974: 49). Note: Group score is based on adding together the total score for each individual and dividing by the number of informants in each group; group mean is based on calculating the mean score for each individual, adding the means together for each group, and dividing by the number of informants in the group.

such as Noun, Verb, and Adjective. Learners identify forms in the input belonging to these categories, and generate linguistic expressions from them. Functional projections such as Inflection, Determiner, and Complementizer are acquired later on the basis of evidence in the L2 input. Importantly, functional categories develop incrementally with those emerging first that immediately dominate the lexical heads, e.g., Inflection, which dominates the verb phrase, emerges before Complementizer, which dominates Inflection. Furthermore, when functional categories first emerge they are minimally specified, e.g., Inflection might be specified for tense before it is specified for subject-verb agreement. Because MT predicts the sequential emergence of categories, different frequencies in suppliance of morphemes realizing functional categories (like those observed by Dulay and Burt and Bailey, Madden, and Krashen) reflect the acquisition of the corresponding underlying syntactic properties. Typically, 60% (or above) suppliance of a form implies acquisition of its syntactic properties (Vainikka and Young-Scholten, 1998).

The second line of theoretical enquiry assumes that both lexical and functional categories are present in early ILGs, either because the language faculty provides them directly as part of its architecture, or because they are transferred from the L1. If learners supply the morphological reflexes of a functional category, whatever their frequency, then the

functional category and its relevant syntactic features have been acquired. But why do learners sometimes fail to supply the morphological reflexes of functional categories? According to the Missing Surface Inflection Hypothesis (MSIH) (Haznedar and Schwartz, 1997; Prévost and White, 2000), L2 learners may select less specified 'exponents' for the output of morphosyntactic operations than would be required in the grammar of a native speaker. To illustrate, *walked* and *walks* are the forms of WALK required when the Inflection category is specified as [finite], and either [past] for *walked* or [nonpast, third-person, singular] for *walks*; *walk* is the exponent inserted elsewhere in finite clauses – it is an underspecified default form. L2 speakers sometimes map the default form *walk* onto [past] or [nonpast, third-person, singular] because L2 speakers are perhaps slower than natives at matching exponents to underlying syntactic representations, especially when speakers are under 'communication pressure' (Prévost and White, 2000) and when nondefault exponents have more complex final consonant clusters (*walked*: /kt/, *walks*: /ks/) than default exponents (*walk*). Nondefault forms may just be too costly in processing terms to select if a speaker's L1 disallows syllable-final consonant clusters (Lardiere, 2000). By contrast, Ionin and Wexler (2002) propose, following Guasti and Rizzi (2002), that if a syntactic operation involves overt movement, this should have a surface morphological reflex. Because copula and auxiliary *be* in English are usually assumed to be verbs that raise to Inflection, they must be morphologically marked on the surface. By contrast, main verbs like *walk* do not raise overtly to Inflection. Instead, tense and subject-verb agreement are associated with main verbs via a covert agreement operation. In such cases, there is no universal requirement to mark covert operations on the surface. Languages differ in whether they do or do not, and language learners have to acquire this on the basis of exposure: "... L2 learners know that morphological expression is obligatory for *be* forms ... but have not mastered the English-specific rules requiring agreement morphology on unraised lexical verbs in certain contexts" (Ionin and Wexler, 2002: 118). Until this rule has been acquired, L2 speakers may treat *-s* and *-ed* as optional. Like MSIH, this account assumes that underlying syntactic representations are more highly developed than oral suppliance of morphological forms.

L2 Acquisition of Derivational Morphology

Although evidence suggests little L1 influence on the development of inflectional morphology, this appears not to be true of derivational morphology. Derivational morphology is typically the surface manifestation of an operation that changes the grammatical class membership of a lexical item, e.g., *-er* signals the change of an item from a verb like *sing* to an agentive noun: *singer*.

Lardiere (1995) tested Spanish and Chinese native speakers' knowledge of derivational morphology in L2 English. English deverbal compound nouns like *dishwasher* are formed from verb-object constructions: *washes dishes*. They show O(bject)-V(erb) order (in contrast to the VO order of the verb construction), and the Object, if a regular plural, loses its *-s*. Spanish deverbal compounds continue to display VO word order and retain the plural *-s*, e.g. *un lavaplatos* (lit. a wash.3sg-dishes) 'a dishwasher.' In Chinese, there is no plural marking and deverbal compounds are either realized by relative clauses or by non-deverbal N-N compounds (Lardiere, 1995: 39, note 18). If properties of the L1 play a role in the development of knowledge of these compounds, we might expect to see a difference in the suppliance of *-s* (Spanish has plural marking, whereas Chinese does not), and in the rate of production of V-N (*washes-dishes*), with the Spanish speakers producing such cases more than the Chinese.

Learners of intermediate to high-intermediate proficiency (L1 Spanish, n = 15; L1 Chinese, n = 11) were presented with questions of the type: "What could you call a person who cleans shoes?," where the expected response is "a shoe cleaner." Results show that there was a significant difference in the production of targetlike English deverbal compounds by Spanish speakers (only 32%) vs. Chinese speakers (62%). Nontarget-like forms consisted of (i) word order errors like V-N, made almost exclusively by the Spanish speakers, and (ii) plural marking of the N, e.g., "a shoes-cleaner" (58% for the Spanish group vs. only 31% for the Chinese group). It appears that morphological properties of the L1 affect development. In particular, Spanish speakers expect deverbal nouns in English to have V-N order and the N to be marked for plural significantly more than the Chinese.

In a further study, Lardiere and Schwartz (1997) found that V-N word order errors decrease over time in Spanish-speaking learners of L2 English (42% for low intermediates, 23% for intermediates and 0.5% for advanced intermediates).

To summarize, L1 influences the representation of derivational morphology in early L2 development, but this influence disappears with proficiency.

L2 Acquisition of Syntax

One potentially impressive kind of evidence that interlanguage grammars develop within limits

defined by an innately determined faculty for language comes from cases where syntactic properties are underdetermined both by L2 input and by properties of a learner's L1. One such property is the Overt Pronoun Constraint, OPC (Montalbetti, 1986). It holds that in languages where an overt pronoun and a null pronoun can alternate freely, only the null pronoun can take a quantified expression as an antecedent, e.g., in Spanish null pronominal subjects (Ø) can alternate with overt pronominal subjects like *él* 'he.' Given a relevant preceding context, (3a), in (3b) both *él* 'he' and Ø in the embedded clause can refer to the referential expression *Juan* 'John' in the matrix clause, as indicated by the coindexing *i*. It also would be possible for both *él* and Ø to refer to an extrasentential antecedent like *Pedro* 'Peter.' In (3b′), the null pronoun Ø can refer to either the quantified expression *nadie* 'nobody,' or even to an extrasentential referent like *Pedro*. The overt pronoun *él* could also refer to an extrasentential antecedent but, crucially, the OPC prohibits the overt pronoun from referring to the quantifier *nadie* 'nobody.'

(3a) Pedro$_j$ y Juan$_i$ están participando en un concurso.
Peter and John are participating in a contest.

(3b) Juan$_i$ cree [que él$_{i/j}$ / Ø$_{i/j}$ ganará el premio]
John thinks [that he / Ø will-win the prize]

(3b′) Nadie$_i$ cree [que él$_{*i/j}$ / Ø$_{i/j}$ ganará el premio]
Nobody thinks [that he / Ø will-win the prize]

Pérez-Leroux and Glass (1997) tested OPC knowledge with English speakers learning L2 Spanish (n = 16) at a very advanced level of proficiency with a minimum of 7 years of experience in Spanish. Eighteen Spanish natives acted as a control group. In a contextualized translation task, natives categorically produced more null pronouns (75%) than overt pronouns (15%) with quantified antecedents. Learners behaved similarly (null pronouns 87% vs overt pronouns 0%), as predicted by the OPC (Table 3). With referential antecedents both groups produced significantly more overt subject pronouns (74% natives, 34% learners) than with quantified antecedents (15% natives, 0% learners), although learners overused null subjects with referential antecedents. Pérez-Leroux and Glass (1997: 159) conclude: "These results indicate a sensitivity to OPC effects in the grammar of highly fluent L2 speakers of Spanish."

Table 3 Proportion of acceptance (%) of antecedents for overt and null pronouns (based on Table 1 by Pérez-Leroux and Glass, 1997)

Antecedent	*Pronoun*	*L2-ers (n = 16)*	*Native Spanish (n = 18)*
Quantified	*él*	0%	15%
	Ø	88%	75%
Referential	*él*	34%	74%
	Ø	58%	24%

Note: The sum of the two conditions (*él* and Ø) in each antecedent context does not always amount to 100% since some of the participants' responses were categorized as 'other,' i.e., a pronominal subject was not produced.

Is the OPC operative at very advanced levels of proficiency only or rather at all levels of proficiency? Pérez-Leroux and Glass (1999) used the same method with three proficiency groups of English speaking learners of L2 Spanish (elementary, n = 39; intermediate, n = 21; advanced, n = 18) and a control group of Spanish natives (n = 20). The production of null subjects across groups (Figure 2) was significantly higher with quantified antecedents (as predicted by the OPC) than with referential antecedents. This suggests that "OPC is operative at all stages in the acquisition of Spanish" (Pérez-Leroux and Glass, 1999: 235).

Crucially, could knowledge of the OPC derive from the Spanish input alone? This seems unlikely. Learners will hear Spanish speakers using: (i) null pronouns with both quantified and referential antecedents; and (ii) *él* with referential antecedents, so nothing in the input prevents them from using *él* with quantified antecedents. Furthermore, if they transferred properties of English, they would allow overt pronouns to refer to a quantified antecedent, because English allows this possibility.

Recent research has uncovered other cases in which L2 knowledge is underdetermined by input, suggesting that innately determined principles of grammar construction are active in the development of L2 grammars, even when acquisition occurs in older learners (White, 2003: Chap. 2).

As for language-specific properties, some appear to be influenced by L1 and some do not. An interesting case of 'differential L1 influence' in syntax is

Figure 2 Percentage of production of null pronominal subjects with quantified and referential antecedents (based on Table 1 in Pérez-Leroux and Glass, 1999).

provided by the acquisition of expletive *it* in English, which is obligatory: *She says it/*ø seems hot today.* Spanish, Greek, Japanese, and Chinese have no expletive pronouns in equivalent cases. However, Japanese and Chinese speakers establish obligatory English expletives more quickly than Spanish and Greek speakers. Zobl (1990) found that Japanese speakers of English at a range of proficiency levels produced hardly any null expletives (ranging from 0% to 18%) in written compositions. A comparison by Zobl between his results and those of Phinney (1987), who tested Spanish speakers at comparable proficiency levels, revealed that Spanish speakers produced null expletives between 50% and 70%. Similar patterns have been widely observed for Spanish/Greek speakers vs. Japanese/Chinese speakers.

Why might this difference occur? It seems to be linked to the fact that null subjects are licensed differently in the two types of languages. Null subjects are licensed via rich person/number verbal morphology in Spanish/Greek (Rizzi, 1997), but via lack of verbal morphology in Japanese/Chinese (Huang, 1984). When speakers of Japanese/Chinese encounter impoverished English verbal morphology to mark person/number (only third-person singular *-s* vs. Ø), their innate language faculty tells them that English does not license null subjects (Yuan, 1997). It would appear that speakers of Spanish/Greek-type languages find it more difficult to determine that person and number morphology on verbs in English is impoverished.

Is L1 syntactic influence on the L2 temporary or persistent? Problems for speakers of Spanish/Greek with obligatory subjects in English appear to be temporary. But in cases in which L1 influence is more persistent, do L2 learners have full access to the resources of the language faculty? To illustrate, consider a case of considerable debate in recent L2 research. Lardiere (1998a, 1998b, 2000) reports a case study of an L1 Chinese speaker with long immersion in English. She found that this speaker in ordinary conversation was fully target-like in supplying pronouns of the right case, Nominative vs Accusative (e.g. *she* vs. *her*), but supplied past tense where it was required in only around one-third of contexts, and third-person singular *-s* on main verbs in less than 5% of cases. Chinese lacks all three of these properties: pronouns do not inflect for case, and verbs do not inflect for tense or subject-verb agreement. Has this speaker then failed to establish an underlying syntactic representation for the features of tense and subject-verb agreement? One answer could be 'yes, she has.' Tense and agreement features may be present in the inventory of syntactic features in the language faculty at birth, but, if they are not selected during L1 acquisition, they become inaccessible at some point during a person's maturation, as in Brown's (2000) finding of persistent failure of L2 speakers to acquire certain phonemes which are not present in the L1. However, Lardiere argues that her informant may just be having a problem mapping past tense and third-person singular present tense forms onto fully-specified syntactic representations, as discussed in the section on inflectional morphology.

It is clear from the evidence presented that L1 influence is considerable but not total in the development of L2 grammars. L2 knowledge is also driven by innate properties of the language faculty, especially when the L2 input underdetermines such knowledge. The picture of SLA that emerges is one of a complex interaction among innate knowledge, previous knowledge from the L1, and input from the L2.

Second Language Attrition

M S Schmid, Vrije Universiteit, Amsterdam, The Netherlands

Introduction

Language attrition is a process which many – linguists and nonlinguists alike – appear to find interesting. Many people feel that, at some point in their lives, they have lost or forgotten some of the competence that they once had in a language, be it a foreign language learned at school or through a sojourn in the country where it was spoken, or a first language which has fallen into disuse for some reason. It is certainly no coincidence that a seminal work on second language (L2) attrition opens with the statement "Language loss affects all of us" (Hansen, 1999). It would be hard to imagine a paper on language acquisition, markedness, or minimalism starting with such a sentence, although it might be equally true.

One reason for this, I would propose, lies in the simple fact that the process of 'un-learning' differs from the process of learning or acquisition (or, for that matter, any other process or aspect of the use of a language) in several ways, but possibly most profoundly on a psychological level: it is an individual (and often lonely) one. While learning a language will almost invariably take place through interaction, through the sharing of a linguistic system that others

Second Language Acquisition: Phonology

J Archibald, The University of Calgary, Calgary, AB, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

This article provides an overview of work on second language (L2) phonology that has been undertaken within a generative framework. The discussion first addresses the acquisition of segments, then the acquisition of syllable structure and of higher level prosodic phenomena. A somewhat selective view of the field is presented, but an extensive bibliography points to additional analyses for those who want to read further. In much of the discussion here, the focus is on the situation that arises when a second language learner is attempting to acquire a structure that is absent from the first language. For an overview of broader issues in second language phonology, see Archibald (1998) or Major (2001).

What Is Acquired?

The first thing to consider in looking at the acquisition of phonology in a second language is the question of what exactly is being acquired. Second language learners must acquire features, segments, moras, syllables, and feet. A theory of phonological knowledge must be adopted; the model in Figure 1 indicates some of the areas that will be examined in the following sections. Let us begin by looking at the acquisition of L2 features.

Figure 1 Phonological structure.

Phonological Features

Brown (2000) argued that if featural representations are lacking from the first language (L1), they will be unacquirable in the L2. She looked at the acquisition of English /l/ and /r/ by speakers of Japanese and Mandarin Chinese (neither language contrasts /l/ and /r/ phonemically). The Japanese situation is diagrammed in Figure 2, where SV represents 'sonorant voice.' In Japanese, [l] and [ɾ] are allophones of a single phoneme. This phoneme may appear only in a simple onset in Japanese. Mandarin Chinese also lacks the contrast (and hence the structure is the same as shown in Figure 2). If the segment is taken to be the level of explanation, then we might predict that both Mandarin and Japanese speakers should be unable acoustically to discriminate /l/ from /r/ (given their L1 feature geometries). In general, however, Japanese speakers are unable to discriminate /l/ from /r/, both acoustically and phonologically (in lexical choice tasks), whereas Chinese speakers discriminate the contrast in both tasks. The graph in Figure 3 shows the overall performance of participants in an auditory discrimination task designed to assess this

Figure 2 Feature geometry of liquids (SV, sonorant voice).

difference. The initial hypothesis, that speakers of both languages would be unable to perceive the /l–r/ distinction because one of the members of the contrast is an L1 phoneme, is not supported by the results (the Chinese speakers could). So, what aspect of the L1 could be accounting for this difference? Brown suggested that a speaker may be able to perceive a nonnative contrast if the feature that distinguishes the two segments is present in the L1 feature geometry (even if the feature is not utilized for the contrast in question). It is the feature [coronal] (Figure 2) that distinguishes /l/ from /r/. The Chinese language requires the coronal node for some sounds but the Japanese language does not. The two language inventories are shown in Figure 4.

Regardless, then, of the L1 liquid inventory, the Chinese speaker will have a representation for the feature [coronal] somewhere in the phonological inventory (i.e., to contrast alveolar from postalveolar segments shown in the box in Figure 4). The Japanese inventory, on the other hand, does not contrast any coronal phonemes and will therefore lack a coronal node. Thus, Brown concluded that L2 speakers cannot build representations for segments that require features not present in their L1. They can, however, combine the features of their L1 in new ways to yield new segments.

Atkey (2000) demonstrated that existing L1 features can be redeployed in new ways in an L2. She looked at the acquisition of palatal stops in Czech by English speakers (she looked at both production and perception but, due to space limitations, only her perception results are discussed here). Czech has two palatal stops, [c ɟ], as well as the alveolar stops [t d], as shown in Example (1):

(1) [tɛka] 'run' (3SG), [cɛka] 'wander'
[dɛkovat] 'to steal,' [ɟɛkovat] 'to thank'

Atkey argued that palatals are phonologically [coronal]. She proposed that the feature required to distinguish the alveolar from the palatal sounds is [posterior]. The Czech structures would be those shown in Figure 5. As a result of the English contrast of three coronal fricative places of articulation, /s, z/ versus /ʃ, ʒ/ versus /θ, ð/, Atkey argued that English has the [posterior] feature. She proposed the representations given in Figure 6. Therefore, English speakers should have the building blocks necessary for acquiring the structure of the Czech palatals. Atkey looked at six North American English-speaking adults who were learning Czech in the Czech Republic. Their exposure to the Czech language ranged from 3 months to 10 years. Learners were given a forced-choice picture selection task that depended on accurate discrimination of alveolar from palatal stops in all syllabic positions. Table 1 indicates the percentage of palatal stops perceived correctly by all learners. Clearly, L2 learners can perform this task at greater than chance levels. Native speaker controls scored 100%. The fact that the learners were much less accurate in final position is due to the reduced saliency of the information on place of

Figure 3 Overall performance on auditory discrimination task.

articulation recoverable at the end of a word. When a stop is released into a vowel, it is much easier for a listener to recover its place of articulation. Atkey's results, then, are consistent with Brown's.

Larson-Hall (2004) also found support for Brown's model when she looked at the perceptual abilities of Japanese speakers learning Russian. She assumed that the Japanese language lacks the underlying features [distributed] and [lateral], both of which are required in Russian. Therefore, it is predicted that the Japanese learners will have the most difficulty discriminating between the sounds [l]/[r] and [ʃ]/[ɕ]. This is exactly what Larson-Hall's study found.

However, the situation may not be as straightforward as the studies have suggested. Work by Curtin *et al.* (1998) documented a case study wherein English speakers learning Thai were able to acquire a feature that is not present in their L1. The property in question is aspiration, which is most likely represented by the feature [spread glottis]. English does not make use of the phonetic feature of aspiration contrastively in its lexical items. Ignoring some complexities, suffice it to say that English has aspirated stops at the beginning of stressed syllables (e.g., 'top' [tʰɑp]) but lacks aspiration after an [s] (e.g., 'stop' [stɑp]). Aspiration, then, in English is predicatable from the phonetic context and does not have to be memorized as part of the word. Thai, on the other hand, utilizes aspiration contrastively. For example, the word [pet] means 'duck' and the word [pʰet] means 'spicy.' English speakers learning Thai, then, would have to learn how to store the feature of aspiration as part of the lexical entry. Curtin *et al.* (1998) argued that English speakers did show the ability over time to lexicalize this phonological feature. That is to say, although their initial structures were transferred from the L1, they were able to trigger new knowledge.

LaCharité and Prévost (1999) proposed a refinement of Brown's model. In looking at French speakers acquiring English, they proposed a hierarchy of difficulty for new sounds. Whereas Brown argued that if a feature was lacking from the L1, then any contrast dependent on that feature could not be acquired, LaCharité and Prévost argued that a missing articulator node would be more difficult to acquire than a missing terminal node would be. French learners of English have to acquire the sounds [h] and [θ]; LaCharité and Prévost proposed the representations of Figure 7 for these sounds. The features in boldface are the ones that are absent from the French inventory. LaCharité and Prévost predicted that the acquisition of [h] would be more difficult than the acquisition of [θ] would be, because [h] requires

Figure 4 Chinese and Japanese phonological inventories.

Figure 5 Czech alveolar and palatal stops.

Table 1 Perception of palatal stops by north American English speakers learning Czech[a]

Percentage of stops perceived by						
Position of stop	*Learner 1 (3 months)*	*Learner 2 (5 months)*	*Learner 3 (11 months)*	*Learner 4 (11 months)*	*Learner 5 (1 year)*	*Learner 6 (10 years)*
Initial	70	90	80	85	80	95
Medial	70	70	80	90	85	90
Final	20	30	50	70	70	80

[a]The length of time each learner had been exposed to the Czech language is shown in parentheses.

the learner to trigger a new articulator node. On a discrimination task, the learners were significantly less accurate identifying [h] than identifying [θ], but on a word identification task (involving lexical access), there was no significant difference between the performance on [h] vs. [θ]. Mah (2003) conducted an event-related potential (ERP) study that looked at English speakers acquiring French and Spanish 'r' sounds. Under her analysis, English lacks a pharyngeal node ([h] being laryngeal), whereas French [R] is analyzed as pharyngeal. Spanish [r], on the other hand, is coronal. The acquisition of both French and Spanish 'r' will require English speakers to activate a new terminal node that Mah defined as [vibrant]. In her analysis of the processing of these two 'r' sounds, Mah did not find any differences between the perception of a French 'r' as opposed to the Spanish 'r.' This is an argument against the LaCharité and Prévost position.

Syllables

Let us turn now to another example of hierarchical structure at a higher level: the syllable. A common model of syllable structure is shown in Figure 8. The languages of the world vary according to such things as whether syllabic nodes can branch. Some languages (e.g., Japanese) do not allow branching onsets or codas. A common phenomenon in second language learning involves modifying an L2 word so that it fits the L1 syllable structure. Consider the English target words and the nonnative speaker's version, given in Example (2), as spoken by someone whose L1 is Arabic (these examples come from Broselow (1988)):

Figure 6 The [posterior] feature in English.

Figure 7 Articulator versus terminal nodes in English.

(2) plant 'pilanti'
Fred 'Fired'
translate 'tiransilet'

Arabic does not allow branching onsets or codas, so an English word such as *plant* cannot be mapped onto a single Arabic syllable. As this example helps show, we can explain why Arabic speakers pronounce English words in the way that they do by investigating the principles of syllabification in the L1. Especially at the beginning levels of proficiency, the structure of the L2 is influenced by the structure of the L1. This would suggest that learners are clearly transferring the L1 principles of syllabification.

Now let us look more closely at the acquisition of consonant clusters. Most of the consonant clusters in the worlds' languages obey what is known as the 'sonority sequencing generalization' (diagrammed in Figure 9), which captures the fact that the nucleus of a syllable is the most sonorous element, and sonority diminishes toward the edges. There are, however, sequences of consonants that violate this generalization, and they tend to involve the phoneme /s/. In English, some s-clusters violate sonority sequencing (e.g., 'st,' because the fricative [s] is more sonorous than the stop [t] is) and some do not (e.g., 'sn,' because the fricative [s] is less sonorous than the nasal [n] is). The analysis of the structure of s-clusters is a complex and problematic area of phonological theory, and the details are not further addressed here. In any case, many researchers argue that [s] is what is known as 'extrasyllabic.' In other words, it is not really part of the syllable, but somehow outside it. The interesting fact, bringing all this back to second language acquisition, is that L2 learners are aware of this.

Carlisle (1997) looked at how Spanish speakers deal with English onset clusters. He noted that three-consonant clusters are changed significantly more often than are two-consonant clusters. Carlisle (1991), in an earlier study on two-segment onsets, found that Spanish speakers modified onsets that violated the sonority sequencing generalization (e.g.,

Figure 8 Syllable structure model.

Figure 9 The sonority sequencing generalization.

st-) significantly more often than they did those that did not (e.g., sn-). Broselow (1992) showed that Arabic speakers treat s-clusters that violated the sonority sequencing generalization differently than they do those that do not, as shown in Example (3):

(3) *sweater* → [siwetar] and *study* → [istadi]
slide → [silayd] and *ski* → [iski]

Singh (1985) demonstrated the same pattern for Hindi speakers (Example (4)):

(4) *fruit* → [firut] and *school* → [iskul]
please → [piliz] and *spelling* → [ispɛliŋ]

Samarajiwa and Abeysekera (1964) showed the same pattern by native Sinhalese speakers pronouncing the Sanskrit words *tyage*, *sriyave*, and *stri* (Example (5)):

(5) tyage → [tiyage] 'gift'
sriyave → [siriyavə] 'grace'
stri → [istiri] 'woman'

These data suggest that L2 learners have full access to the principles of sonority sequencing, regardless of their L1 experience.

The work of Eckman and Iverson (1993, 1994) also clearly demonstrated that syllable structure can be changed in L2 learning. People can learn to pronounce new clusters that are not found in their L1. Abrahamsson (2003) provided one of the best overviews of the studies into the second language acquisition of syllable structure. He focused on the patterns of acquisition in coda position. Abrahamsson looked at the different types of repair strategies that are available to a learner whose L1 does not sanction coda consonants. Two strategies that are covered are epenthesis and deletion. Consider Example (6), which shows the target words, the deleted forms, and the epenthesized forms, respectively:

(6) when [wɛ] [wɛnə]
wet [wɛ] [wɛtə]
went [wɛ] [wɛntə]

As Example (6) illustrates, the deleted forms ([wɛ]) are much more difficult to recover for the listener than are the epenthesized forms. Abrahamsson hypothesized that the proportion of epenthesis to deletion repairs will increase as a learner's overall proficiency increases.

Abrahamsson also looked at speakers of Chinese (a language that allows at most one consonant in the coda) learning Swedish (which allows – or as Abrahamsson put it, has a "pain threshold of" – five consonants at the end of a word). Learners were recorded nine times, with 3 to 5 weeks between recordings. The first recording took place 10 to 24 days after the learners arrived in Sweden. The tenth recording took place 1 year after the ninth recording. For all three learners, the proportion of epenthesis to deletion increased over time (Figure 10). Furthermore, Abrahamsson showed that learners modified (epenthesis and deletion) inflected forms significantly more often than they did monomorphemic lexical forms. In addition, learners used epenthesis as a repair strategy more often on monomorphemic lexical items than they did on inflected items, as shown graphically in Figure 11. They also used inflection more often on open class lexical items than on closed class lexical items. Abrahamsson proposed a functional explanation for this: that there is a greater possibility for ambiguity in open class words than in closed class words and therefore recoverability will be

Figure 10 Proportion of epenthesis and deletion over time (modification strategies) for three Chinese-speaking learners (C1, C2, and C4) of the Swedish language.

Figure 11 Error type in different grammatical categories, produced by three Chinese-speaking learners (C1, C2, and C4) of the Swedish language.

Figure 12 Overall error rates of Chinese speakers producing English monosyllables.

enhanced for the listener by epenthesizing the open class words. As there are fewer lexical competitors for closed class words, the subjects are freer to delete sounds from them, and the message will still be conveyed.

Lin (2001) presented another take on the syllable simplification strategies used by second language learners. Lin looked at the effects of different tasks, or different register as stimulated by a given task, on the accuracy of consonant cluster production. She argued that more formal registers do not lead to greater accuracy, as had been suggested in other studies (e.g., Tarone, 1983), but rather that the formality of the register correlates with the type of repair strategy used. She suggested that epenthesis is used relatively more often in more formal contexts (when focus is on the form of the utterance, rather than on the content). Conversely, deletion and substitution will be used relatively more often in less formal contexts. In the study, she looked at 20 Chinese speakers producing a variety of two-consonant onset clusters (e.g., [pj], [dr], [fl], [sn]) in English monosyllables. The speakers were taught the meanings of a variety of words (and pseudowords) and were given 15 minutes to learn them and practice pronouncing them. The four tasks were (1) reading minimal pairs with normal orthography and phonetic transcription, (2) reading randomized lists of target words in normal orthography, (3) reading two sentences out loud in a grammaticality judgment task, and (4) controlled conversation or structured interview. Task number one was assumed to be the most formal, moving down the scale to task four, which was assumed to be the most casual. There were no significant differences in overall error rates for the four tasks, as shown in Figure 12. However, as predicted, there was a significant decrease in the amount of epenthesis as the task formality decreased, as shown in Figure 13.

Moras

At another level of phonological structure, the moraic level, as shown by Broselow and Park in their work (1995) on mora conservation in L2 phonology, we see also that learners transfer their L1 phonological structures. Broselow and Park began by presenting the pronunciation data given in Examples (7a) and (7b), obtained from native speakers of Korean who were learning English:

(7a)	bit^{h}ɨ	'beat'
	čip^{h}ɨ	'cheap'
	p^{h}ik^{h}ɨ	'peak'
	rut^{h}ɨ	'route'
	k^{h}ot^{h}ɨ	'coat'
(7b)	bit	'bit'
	t^{h}ip	'tip'
	p^{h}ik	'pick'
	gut	'good'
	buk	'book'

Note that, the Korean speakers insert an epenthetic [ɨ] at the end of each word in Example 7(a), but not at the ends of the words in Example (7b). The first three words in the two examples end in the same consonants, so the epenthetic insertion cannot simply be triggered by the final consonant in the English word. Broselow and Park suggested that it is the quality of the vowel in the English root that determines whether epenthesis takes place. The epenthetic vowel is added to words that have long (bimoraic) vowels and not to words that have short (monomoraic) vowels. What would cause this difference in behavior? Broselow and Park (1995) assumed coda obstruents are nonmoraic in Korean. Syllabic nuclei must be

Figure 13 Epenthesis in different tasks.

Figure 14 Mora. (A) Representation that includes a bimoraic vowel. (B) The second mora is delinked from the vowel, leading to epenthesis (C).

monomoraic in Korean (contrasted with English, in which they may be either mono- or bimoraic). In their view, the L2 learner begins by perceiving the L2 English input of a word such as 'beat,' and then setting up a representation that includes a bimoraic vowel, as shown in Figure 14A. Because this is an illicit structure in Korean, the second mora is then delinked from the vowel, as in Figure 14B; this triggers epenthesis, which fills the empty mora, and then onset formation occurs as in Figure 14C. Broselow and Park argued, then, that what the Korean learners are doing is attempting to preserve the mora count of the original English word (which has two moras attached to the vowel). Because this is an illicit structure in Korean, the learners set up a new syllable that allows the bimoraic structure to be preserved.

Stress

The question of L2 learners acquiring stress has been addressed in a number of projects. The broad conclusions suggest (1) that adult interlanguages do not violate metrical universals, and (2) that adults are capable of resetting their parameters to the L2 setting. The learners are quite good at putting English stress on the right syllable. Thus, their interlanguages are a combination of universal grammar principles, correct L2 parameter settings (from resetting), and incorrect L1 parameter settings (from transfer).

Table 2 illustrates how languages may differ in their parameter settings. When the parameter settings are different in the first and the second languages, we have the potential for transfer. Often, the L1 parameter settings transfer into the L2. Studies by Archibald (1993) showed that L2 learners were able to reset their existing parameters to new values. Van der Pas and Zonneveld (2005) argued against the parameter resetting analysis. However, it was less clear as to whether learners whose first languages did not have stress, but rather had tone, were able to trigger these metrical representations. Archibald (1997a) argued that Chinese and Japanese speakers learning English did not compute metrical representations, but rather stored stress placement for each lexical item. Ou and Ota (2004) argued that Chinese learners of English show sensitivity to syllable weight in a perception test of English words and hence that these learners are able to engage in a computational process to generate stress placement. This would be further evidence that second language learners are able to create new representations that are not found in their L1.

Rhythm

Whereas pedagogic treatments of L2 rhythm abound (primarily focusing on the differences between so-called stress-timed and syllable-timed languages), there have been relatively few empirical studies of

Table 2 Metrical parameter settings for different languages[a]

Parameter	*Spanish*	*Polish*	*Hungarian*	*English*
P1 (word tree)	Right	Right	Left	Right
P2 (foot type)	Binary	Binary	Binary	Binary
P3 (built from)	Right	Right	Left	Right
P4 (strong on)	Left	Left	Left	Left
P5 (quantity-sensitive)	Yes	No	Yes	Yes
P6 (sensitive to)	Rhyme	NA[b]	Nucleus	Rhyme
P8 (extrametrical)	Yes	No	No	Yes
P8A (extrametrical on)	Right	NA	NA	Right

[a]The parameters are considered part of universal grammar: values for each language determine how stress placement is assigned. L2 learners may transfer the settings of their L1 onto the grammar of the L2.
[b]Not applicable.

this phenomenon. Guilbault (2002) investigated the acquisition of French rhythm by English L2 learners. French has been argued to be a language wherein there is much more equal duration of syllables (syllable timed) than there is in English (stress timed). Guilbault argued that advanced L2 learners of French have modified the temporal properties of their speech to approximate its rhythmic patterns.

Intonation

There are very few studies on the acquisition of L2 intonation carried out within a generative framework. To understand why this would be the case, we need merely go back to the question posed at the beginning of this article: what is being acquired? In order to understand how syllable structure is acquired, we need to have a model of what syllable structure is. In order to understand how people arrive at knowledge of intonation in a second language, we need to have a model of what exactly native speakers of a language know when they can produce and perceive intonation patterns in their first language. And this is where we find relatively little agreement in the generative literature (for a discussion, see Ladd (1996)). One exception is the work of Jilka (2000). Working within the tone and break index (ToBI) system, Jilka demonstrated that a nonnative intonation pattern is a robust cue to nonnative-like phonology. Native speakers of English were recorded speaking German, and native speakers of German were recorded speaking English. All subjects were assessed as having high levels of proficiency and high levels of segmental accuracy. For all subjects, the nonnative utterances were 'corrected' by an automated program. Both raw and corrected versions of the sentences were played (nonsequentially) to native speaker judges. A significant number of the native-speaking judges judged the corrected versions to be more nativelike than the raw versions were.

Summary

When we probe the construct of second language accent, we can demonstrate the complexity of the phonological grammars of language learners. Linguistic theory and the field of second language acquisition combine to explain the nature of the mental representations that underlie second language speech.

Second Language Acquisition of Phonology, Morphology, and Syntax

R Hawkins, University of Essex, Colchester, Essex, UK

Introduction

Four questions have dominated recent research in second language (L2) acquisition: (i) What role does a speaker's first language (L1) play? (ii) Does L2 acquisition display developmental patterns that are similar across learners? (iii) Is an innately determined human language faculty involved? (iv) Why is knowledge of an L2 sometimes underdetermined by the input? This article reviews some of the empirical findings bearing on these questions in the domains of L2 phonology, morphology and syntax, and considers how answers might contribute to the construction of a theory of L2 acquisition.

L2 Acquisition of Phonology

Casual observation tells us that most speakers of an L2, where acquisition has occurred beyond childhood, have foreign accents. Is this the consequence of the pervasive influence of a speaker's L1? With some properties of L2 phonology there is early, but temporary, L1 influence, with others L1 influence is persistent, and with yet other properties the influence comes from universal principles of phonological organization.

Broselow (1983, 1988) offers a clear case of L1 influence. Native speakers of Egyptian and Iraqi Arabic, in their production of syllable-initial English consonant clusters, may insert an epenthetic vowel; i.e., a vowel that creates an extra syllable. Interestingly, Egyptian Arabic speakers insert it in a different position from Iraqi Arabic speakers (**Table 1**) as a result of their L1 Arabic syllable structure.

Second Language Attrition

M S Schmid, Vrije Universiteit, Amsterdam, The Netherlands

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Language attrition is a process which many – linguists and nonlinguists alike – appear to find interesting. Many people feel that, at some point in their lives, they have lost or forgotten some of the competence that they once had in a language, be it a foreign language learned at school or through a sojourn in the country where it was spoken, or a first language which has fallen into disuse for some reason. It is certainly no coincidence that a seminal work on second language (L2) attrition opens with the statement "Language loss affects all of us" (Hansen, 1999). It would be hard to imagine a paper on language acquisition, markedness, or minimalism starting with such a sentence, although it might be equally true.

One reason for this, I would propose, lies in the simple fact that the process of 'un-learning' differs from the process of learning or acquisition (or, for that matter, any other process or aspect of the use of a language) in several ways, but possibly most profoundly on a psychological level: it is an individual (and often lonely) one. While learning a language will almost invariably take place through interaction, through the sharing of a linguistic system that others

already possess, through entering some linguistic community – whether the artificial one of the foreign language classroom, or the real-life one in the country where it is spoken – and through communication, attrition is felt most keenly (although by no means does it have to be most drastic) where these factors are absent, where there is isolation from the language. It is my belief, born out of many interactions with people who feel that their competence in a language has 'attrited,' that this loneliness and isolation may, paradoxically, often lead the speaker to feel an authenticity and involvement about this process that is lacking in the more natural, common sense and communicative process of language acquisition.

While this aspect certainly adds to the compelling human interest of the topic, and is vital for the researcher to bear in mind when investigating attrition (a language that the speaker feels has attrited can be a very vulnerable spot in the first place, but if it is also an intimate territory that is easily violated, care and sensitivity are vital if one would avoid doing emotional damage), it may also be responsible for having biased research towards somewhat easy approaches and simplistic explanations over the past decades. It cannot be a coincidence that metaphors such as 'derelict houses,' 'riding a bicycle,' 'trying to find a lost possession,' to name but a few, abound in language attrition research. We know language to be an extraordinarily complex, multilayered neuropsychosociological system that very probably bears no resemblance whatsoever to a house, a bicycle, or a set of keys that we may have lost. However, there seems to be a profound need to think what we know – or think we know – to be true, authentic, and part of our own emotional experience, which we can also grasp and understand intellectually. It is often when this need is thwarted that we reach for metaphors that can explain what we cannot interpret within its own frame of reference.

The term 'language attrition' itself was clearly born out of such a metaphor: the OED defines attrition as "the action or process of gradually reducing the strength or effectiveness of someone or something through sustained attack or pressure." This indicates that the term was coined on the assumption that a linguistic system in disuse will be vying for memory space with the other linguistic system(s) occupying the same brain, that not being kept fresh and strong through constant use will somehow weaken it, and that it will therefore suffer in some way. Whatever deviant forms were observed in the attrition process were therefore implicitly assumed to be the result of another language encroaching on the linguistic system and changing its representation. It should be stressed that at the time that the term 'attrition' was first used, in the early 1980s, there was absolutely no evidence whatsoever for such a process (arguably, there still is none), and one should remember that the explanation engendered in the label was purely intuitive. The fact that the term has caught on, even though some still object to it very decisively (e.g., V. Cook, personal communication – such objections, however, are usually based more on the negative semantic potential the term carries than on the inaccuracy of the metaphor), further seems to indicate that this metaphorical explanation was intuitively convincing to many.

This underlying perspective changed as psycholinguistics and neurolinguistics began to take an increased interest in language attrition. It quickly became evident that many of the phenomena witnessed in attrition could not simply be explained on the basis of interference from another language. The forces governing attrition began to be ascribed more to a language internal process, due to lack of exposure or input in that language, not through the amount of exposure to or input from another. Even more recently, the role of output has also been stressed in this connection (de Bot, 2001: 70). And ever since it has become evident that there is more to the process of language attrition than a situation of hostile takeover by another language, researchers have been looking for theoretical models that might have the power to make sense of the puzzling phenomena witnessed in the process of attrition.

Theoretical Models

As mentioned above, one of the most important forces in both L1 and L2 attrition has always been assumed to lie in cross-linguistic influence (CLI). For L1 attrition, the investigation of this phenomenon is relatively straightforward, since one can assume that CLI was relatively minor or completely absent before the onset of attrition, that is, before the move to another environment takes place. For L2 attrition, on the other hand, it can be difficult to investigate the increase of CLI, since L1 probably always has some degree of influence on L2. It is therefore necessary either to isolate phenomena that are known to have been mastered at some time, or, ideally, to choose a longitudinal research design, where the development of certain selected features can be monitored over a longer time span (on the influence of time on attrition, see below).

One of the more intuitively persuasive models to be invoked in language attrition research was also one of the earliest ones: the regression hypothesis, first formulated by Ribot, extended to aphasia by Freud, and formulated more specifically in this context by Jakobson in

the 1940s, in particular with respect to phonology. This theory, also known as the LIFO (*last in, first out)* model, predicts that the process of loss of a language will be the reversal, or mirror image, of the process of acquisition. In other words, it assumes that we forget things in the inverse order in which we learned them, that the things we acquired earliest will be most persistent, while more recent knowledge will be more vulnerable.

As has often been pointed out, where pathological language loss is concerned the regression hypothesis does not provide a valid theoretical framework. However, the findings from L2 attrition research suggest that order of acquisition may be a valid predictor for the attrition process – order of acquisition, in this case, not referring to normal and unguided child language acquisition, but to the order in which the individual who is forgetting an L2 learned the features under investigation in the classroom (Berko-Gleason, 1982; Cohen, 1975; Hayashi, 1999; Jordens *et al.*, 1986, 1989) or in unguided exposure to an L2 environment (Cohen, 1989; Hansen, 1999; Kuhberg, 1992; Olshtain, 1989). As Hansen points out, in L2 attrition the question is no longer **if** the regression hypothesis applies, but "**when** and **under what conditions** its predictions hold true" (1999: 150, her emphasis).

A further interesting question to ask in this context is, of course, why. What is it in the acquisitional sequence that would have such a strong influence on language forgetting? Is it due to some intrinsic feature of linguistic knowledge and its organization in the brain (as was the original assumption)? Is it due to reinforcement, or lack thereof – features that have been acquired recently will not have been rehearsed as frequently as the early features (quality of learning vs. chronology of learning, cf. Obler, 1993: 189; Weltens, 1988: 7; Yoshitomi, 1994: 12)? Or does it have to do with the linguistic complexity of particular items and features; especially in classroom acquisition of an L2, one would assume that the simpler grammatical phenomena are taught earlier, while the more complex ones, which will be reserved for later and will be harder to master, will also be more difficult to maintain (Andersen, 1982: 113)? This factor has not yet been resolved.

Another linguistic theory that is often invoked in L2 attrition is markedness, most usually in the UG sense of the term (*see* **Linguistic Universals, Chomskyan**; Hansen, 1999; McCormack, 2001, 2004). This theoretical framework assumes that language-internal processes, such as those addressed in Chomsky's theory of government and binding (GB), can predict the sequence of language attrition. As Sharwood Smith and Van Buren (1991: 17) point out, it seems important to know whether an individual has lost or **is even able to lose** those kinds of underlying mental representations of an attriting language that may be identified as Chomskyan-style Universal Grammar (UG)-based competence. This is based on the assumption that second language learners only have access to a UG that is already parameterized. With respect to L2 attrition, the prediction would thus be that a marked value that the second language learner has acquired will, in the process of language loss, revert to its unmarked L1 setting. Such a process has indeed been identified by McCormack (2001, 2004), with the intriguing twist that the linguistic feature under investigation (the binding properties of the English reflexive) began to be influenced by another linguistic category (finiteness), which does not influence the feature in either of the attriter's languages, but does play a role in other natural languages.

These are the most important linguistic models for L2 research; other theoretical approaches have been applied to the development of certain linguistic features in L1 attrition; for an overview see Köpke and Schmid (2004).

Extralinguistic Factors

The process of language attrition is influenced not only by linguistic factors, but also by extralinguistic ones such as age at onset of attrition, achievement level at onset of attrition, time since onset of attrition, amount of exposure to the attriting language, attitudes and motivation, etc. For L1 attrition, a further important factor is education level. Where the study of L2 attrition is concerned, this factor usually has relatively minor influence, since often the same level of achievement in L2 presupposes a similar education level. Education will therefore not be included here: a discussion can be found in Köpke and Schmid (2004).

An important extralinguistic variable for the study of L2 attrition is attitude and motivation. Since this has been shown to be one of the most important determining factors for success in L2 acquisition (*see* **Motivation and Attitude in Second Language Learning**), it would be only natural to assume that it might also condition retention. However, attitude has proved to be a slippery diagnostic in attrition studies, probably partly because such studies typically cover a longer range of time than studies of acquisition, and attitudes are subject to frequent and often radical changes (Schmid, 2004a). So far, the only studies that were able to correlate attitudinal and attritional factors were those that measured attrition exclusively by self-evaluations (L1 attrition: Waas, 1996; L2 attrition: Gardner *et al.*, 1985, 1987). However, self-evaluations often are not a valid predictor of the

actual attritional process, especially in L2 attrition speakers, who tend to report massive losses that are not borne out by actual linguistic tests (Weltens, 1988).

Where age at the onset of attrition is concerned, findings so far suggest that there is an important turning point that probably can be situated somewhere between 8 and 10 years. Virtually all studies of both L1 and L2 attrition that investigate children around or below that age report a significant decrease in proficiency, while studies using older subjects often establish a surprising degree of stability in linguistic knowledge. Especially interesting in this context are the findings of Berman and Olshtain (1983) and Fujita (2002). Both of these studies suggest a freezing point or cutoff point around age 9, which proved the strongest determining factor for their investigation. Similar findings have been reported for L1 attrition (for an overview, see Köpke and Schmid, 2004). It is very interesting to note that this cutoff point in most cases coincides with the age at which children master literacy. The question of whether the stabilization of the linguistic system is conditioned purely by brain maturation processes that occur at that age or whether it may be caused or at least facilitated by literacy has recently been posed (Hansen, 2001; Köpke, 2004; Köpke and Schmid, 2004), but remains unresolved. (*see* **Phonological Awareness and Literacy**.)

Level of achievement, on the other hand, is a factor which plays a much greater role in the study of L2 attrition than it does for adult L1 attrition, where usually the process of normal acquisition of the feature(s) under investigation is assumed to have been completed prior to the onset of attrition. For L2 attrition, however, a critical threshold or critical mass (Nagasawa, 1996, 1999), after which L2 proficiency appears to stabilize, has often been suggested. Numerous further studies, while not going as far as proposing such a threshold, have found the level of initial proficiency (that is, proficiency at the time where instruction in or exposure to the L2 ceases) to be the best predictor of language loss or retention (e.g., Reetz-Kurashige, 1999). Interestingly, Hansen (1999) established the impact of length of exposure to L2, as opposed to initial level of proficiency. This factor has not been tested elsewhere, but it can be expected that length of exposure and proficiency will usually depend on each other. It has thus often been suggested that a higher proficiency in L2 is a good safeguard against attrition. In this context, an intriguing observation was made by Bahrick (1984) and Weltens (1988): their findings suggest that L2 learners will relatively quickly lose a fixed amount of knowledge, independent of their initial level of proficiency. However, while this means that both high and low proficiency speakers of L2 lose the same amount in **absolute** terms, **relatively** speaking each speaker has a lower proportion of knowledge at the onset of attrition.

A further finding from these latter two studies refers to the time period in which this loss takes place. As has also been suggested for L1 attrition, it seems that the greatest part of L2 attrition takes place within the first few years immediately following the end of instruction in or exposure to L2. The earliest major study of L2 attrition, Bahrick (1984), suggests that the lion's share of L2 attrition can be found within 3–6 years. After this, his findings suggest surprising longevity of linguistic knowledge. The part of this knowledge that will remain robust for approximately 25 years he labels permastore content, while another large part appears to be completely impervious to language attrition.

Linguistic Levels

Many attempts have been made to describe exactly which linguistic features are more vulnerable to loss, i.e., belong to the linguistic knowledge that will disappear in the early stages of language attrition, and which of them will belong to the more robust part of the linguistic repertoire. In both L1 and L2 attrition, it is generally agreed that the lexicon – or part of the lexicon – will suffer most easily and quickly. Whether such a reduction is a case of actual loss, or simply a matter of diminished accessibility, has often been debated, but the fact that many studies have found receptive skills to be unimpaired (e.g., Grendel, 1993; Weltens, 1988) suggests the latter.

How productive lexical skills, on the other hand, are affected by attrition seems to be influenced by frequency and similarity. It has often been pointed out that low-frequency lexical items tend to become inaccessible before high-frequency ones, and that cognate items are retained better. These findings are exactly what common sense would lead us to expect. While investigating the attrition of lexical skills may help us understand memory processes or the organization of the mental lexicon (*see* **Neurolinguistics from the Middle Ages to the Pre-modern Era**), there seems to be little we can learn from such studies in terms of the structure of linguistic knowledge. For this reason, more recently, language attrition has focused more on grammatical aspects.

The erosion of grammatical and phonological skills, too, has often been assumed to be influenced by similarity between the two languages. In these areas, frequency does not play an important role (most grammatical and phonological features occurring

very frequently in most types of discourse), and research has usually focused on complexity instead.

While there is a small body of work dealing with the impact of attrition on L2 phonetics (e.g., Dugas, 2000 on voice onset time and Nagasawa, 1996 on pauses), the attrition of L2 phonology remains very much under-researched. The only detailed investigation to have been conducted thus far focused only on receptive skills, where the impact of similarity between L1 and L2 was conclusively demonstrated (Weltens, 1988). Studies investigating, for example, the development of the production of phonemes not present in L1 are clearly called for. The large body of work on L2 acquisition of phonological features would be very useful in this context (*see* **Second Language Acquisition: Phonology, Morphology, Syntax; Second Language Acquisition: Phonology**).

Such studies could help elucidate the impact of similarity or dissimilarity between L1 and L2, which remains a contested matter. While in the earlier stages of language attrition research, the prevailing assumption was that items that are also present in an attriter's stronger language would be easier to preserve in the attriting language, this has more recently been called into doubt, especially where the grammatical system is concerned. It is tempting to assume that the presence of a feature in L1 will lead to its frequent rehearsal and thus prevent attrition of the same feature in L2. However, as two grammatical or phonological features, or even two cognate lexical items, are rarely if ever totally identical in two languages, this is a double-edged sword: it is also possible that the slightly different use, pronunciation, or meaning of the grammatical, phonological, or lexical feature under investigation will imprint itself on the comparable feature in L2, and thus lead to its misuse (this would be congruent with the early, intuitive meaning of the term 'attrition' mentioned above). At the same time, features of L2 that are not similar to anything that L1 has, such as English /θ/ or /ð/ for L1 speakers of Dutch or French, might be immune to such attritional forces (*see* **Second Language Acquisition: Phonology**).

To illustrate this last point, consider the case of past tense morphology. Both English and German have a synthetic past tense (formed by suffixation of the verbal stem) and a periphrastic one (formed with an auxiliary verb and the past participle of the main verb). However, while in English these two are clearly distinguished aspectually, in German no such distinction exists, and the distribution is mainly stylistically conditioned (*see* **Aspect and Aktionsart; Tense, Mood, Aspect: Overview**; see also Schmid, 2002: chap. 5.1). Consider the following example:

(1a) I did not go home.
(1b) I have not gone home.

In English, (1a) could only be part of a narrative, which at the point of telling is concluded: wherever the narrator had been going, he or she would be expected to have reached the destination at the moment of narration. Example (1b) suggests that he or she is still on her way, and will, at some point in the future, go home.

In German, however, one would expect the sentence grammatically corresponding to (1a) to occur in a written, formal or literary narrative, while (2b) would sound more natural in a spoken, colloquial one. There is no aspectual distinction between (2a) and (2b).

(2a) Ich ging nicht nach Hause.
(2b) Ich bin nicht nach Hause gegangen.

An investigation of this grammatical feature in language attrition would first have to come to a workable definition of similarity. Grammatically speaking, both languages possess the same feature; however, the meaning potential is different. So we might, for example, expect both L1 or L2 speakers whose German is attriting and whose English is dominant to reject (2a) in a context where the aspectual prerequisites that condition the use of the corresponding English structure are not met.

The methodological catch here is that it is a logical impossibility to establish the impact of (dis)similarity of a particular feature on the basis of only two languages. In order to investigate such a feature, it is necessary to include a cross-linguistic comparison with at least one other language. A possible candidate would be French, which has a three-way contrast that marks both aspectual and stylistic differences morphologically: the synthetic past tense in (3a) indicates a continuous aspect, the periphrastic one in (3b) suggests completion, while the synthetic tense in (3c) replaces the periphrastic tense in literary or formal contexts.

(3a) Je ne retournais pas à la maison.
(3b) Je ne suis pas retournée à la maison.
(3c) Je ne retournai pas à la maison.

It is this kind of contrast that would be interesting to investigate comparatively, in order to gain more information on the impact of similarity and contrast in language attrition, particularly where L2 is concerned.

Research Designs

It has recently been pointed out how important it is to recognize that the way in which data are elicited and the way in which certain linguistic features are

selected in particular studies of language attrition will determine and limit the conclusions to be drawn (Köpke and Schmid, 2004). In this respect, it is vital to recognize fundamental differences between L1 and L2 attrition. All aspects of language attrition research discussed so far have an impact on both L1 and L2 attrition, the differences are usually merely quantitative. It is where research designs are concerned that the division between the two fields becomes qualitative and not comparable.

This is understandable, since the skills acquired in both acquisition processes are probably very different, and so it takes different tasks and tests to measure their erosion as well as their acquisition (*see* **Assessment of Second Language Proficiency**; **Assessment of First Language Proficiency**).

However, L2 attrition can further be separated into two clear subfields, namely that of an L2 that was acquired through formal, classroom teaching (often, this means that it has hardly, if ever, been used in a naturalistic setting) and an L2 acquired informally through a sojourn in the country where the language was spoken. While earlier studies, such as Bahrick (1984), Weltens (1988), and Grendel (1993) focused on the former type, recently focus has shifted to the latter, particularly in the large body of studies focusing on Japanese returnees or former missionaries in Southeast Asia (e.g., the studies collected in Hansen, 1999).

An interesting case in point is the study by Murtagh (2003), who investigated the L2 attrition of Irish Gaelic. While this language had been a compulsory subject for all her informants at school, it is not quite clear how subjects' exposure to this language in childhood, e.g., from a grandparent, might influence the process of attrition. A similarly mixed situation is also investigated by Montrul in the case of heritage speakers of Spanish, and it seems clear that this distinction has the potential of confounding the issue unless it is given more prominence in L2 attrition research.

While L1 attrition studies often attempt, through informal conversations or semi-structured interviews, to elicit data that is as naturalistic as possible and thus matches the skills an L1 speaker can be assumed to possess, L2 attrition research has mainly relied on the methods developed for the assessment of L2 proficiency. In the case of a formally acquired L2, the logic behind this approach is compelling, since it allows the best comparison with the point of reference at the onset of attrition (ideally in a pre-test post-test design, if information about the informant's performance at this point is available, or through use of data obtained in a similar way from a control group). Often, such tests have even been standardized across large populations and can thus be considered to be particularly valid, and also have the further advantage that they are in a format that everyone exposed to L2 teaching is familiar and comfortable with.

However, when dealing with speakers who have acquired their L2 informally, these methods have their limitations. The first and most obvious one of these is that many such tests rely heavily on written material (with the great advantage that they can be administered to large groups of informants at a time). Speakers who have never had formal instruction in a language often have very limited literacy, especially in languages that use a different writing system than their own; and even in cases where they are literate, the gap between spoken and written skills is usually much greater than in the other type of L2 acquisition (where speakers often even prefer the written to the spoken code).

The second problem is that, while such standardized methods test skills that can be clearly assumed to have been learned after a certain time of systematic instruction, assessing the point of reference, i.e., the proficiency of an informant in a particular skill at the onset of attrition, is much more difficult for speakers who have never had any formal language teaching, since there is great individual variance in such cases. For such groups, thus, a longitudinal research design would be ideal. Nevertheless, considering Bahrick's (1984) findings about permastore content that remains stable for 25 years or more, one has to wonder just how practical such a design would be.

An investigation of testing techniques used in L2 attrition studies clearly reveals the shift in focus from the attrition of a formally to an informally learned L2: while virtually all studies that were conducted in the 1980s used measures such as cloze tests and other formal exams, many studies in the 1990s worked with free conversations or data elicited through picture-story retellings. (An annotated bibliography of studies of both L1 and L2 acquisition, detailing languages investigated, theoretical frameworks, and test methods can be found in Schmid, 2004b.)

Obviously, the manner of data elicitation can only ever be evaluated alongside a fair consideration of the goals pursued, since they permit very different conclusions. Naturalistic methods are ideal for global approaches, aimed at measuring all aspects of performance, or for preliminary research in order to identify sensitive areas. More formal tasks, on the other hand, allow for better control of linguistic and psycholinguistic factors and should thus be applied in the investigation of specific domains.

Most of all, it should be acknowledged that the attrition of a formally and informally acquired L2 probably makes up two separate and different

areas of study. This difference could be far more important and useful than the four-way classification of language attrition by attriting language and environment, which was first proposed by de Bot and Weltens (1985) but is usually ascribed to van Els (1986). This taxonomy is still invoked at the beginning of virtually every article on language attrition, although its practical impact has been negligible.

Conclusion

The study of language attrition, and in particular of L2 attrition, has come a long way, from the mostly descriptive approaches that dominated in the 1980s to the quantitative and theoretically informed studies of the past decade or so. More work is clearly needed in this expanding domain, since language attrition is a topic that is not only intuitively interesting. Like the study of a language being acquired, investigating a language that is in a process of decline can help us gain insights that a normal linguistic situation would not allow. But then again, what is normal? As the quote toward the beginning of this article states, "[l]anguage loss affects us all." If properly investigated, however, it can benefit us all as well.

Second Language Listening

Introduction

It was not until well into the second half of the 20th century that second language listening was widely recognized as a skill that could and should be systematically developed and assessed by those teaching a second language. Whereas earlier scholars such as Henry Sweet and Harold Palmer had stressed the importance of teaching the spoken language, in their view such teaching was to be based on "the science of phonetics," which effectively meant that the aspect of the spoken language actually taught was its pronunciation. It seems that these scholars supposed that, if you could pronounce the target language reasonably well, it must follow that you would be able to understand it when you heard it spoken. So, in early work on listening comprehension based on the structuralist tradition, it was assumed that the main problems in second language listening would be a mirror image of problems with pronunciation. Students were systematically taught to identify differences between those sets of vowels or consonants in the target language that a contrastive analysis of the phonological systems of the L1 and L2 predicted would be difficult for the L1 speakers to distinguish in L2 speech. Students listened to triplets of words, such as *bit bit beat* or *try dry try*, and were required to identify which of the three words was different from the other two. They listened to sets of words with similar consonantal and vocalic structure but different stress patterns and identified those with different stress patterns. And they listened to phrases like *the pink one* uttered with either falling or rising intonation and identified the one with rising intonation as a question.

With the advent of mass tourism in the 1960s, the gulf became glaringly apparent between being able to identify a sequence of words spoken slowly and carefully in the foreign language and being able to identify words in the acoustic blur of normal conversational speech. As Wilga Rivers (1968: 135) remarked, emphasis in language teaching had hitherto been placed on students' production of the language, disregarding the fact that communication takes place between (at

Second Language Listening

Introduction

It was not until well into the second half of the 20th century that second language listening was widely recognized as a skill that could and should be systematically developed and assessed by those teaching a second language. Whereas earlier scholars such as Henry Sweet and Harold Palmer had stressed the importance of teaching the spoken language, in their view such teaching was to be based on "the science of phonetics," which effectively meant that the aspect of the spoken language actually taught was its pronunciation. It seems that these scholars supposed that, if you could pronounce the target language reasonably well, it must follow that you would be able to understand it when you heard it spoken. So, in early work on listening comprehension based on the structuralist tradition, it was assumed that the main problems in second language listening would be a mirror image of problems with pronunciation. Students were systematically taught to identify differences between those sets of vowels or consonants in the target language that a contrastive analysis of the phonological systems of the L1 and L2 predicted would be difficult for the L1 speakers to distinguish in L2 speech. Students listened to triplets of words, such as *bit bit beat* or *try dry try*, and were required to identify which of the three words was different from the other two. They listened to sets of words with similar consonantal and vocalic structure but different stress patterns and identified those with different stress patterns. And they listened to phrases like *the pink one* uttered with either falling or rising intonation and identified the one with rising intonation as a question.

With the advent of mass tourism in the 1960s, the gulf became glaringly apparent between being able to identify a sequence of words spoken slowly and carefully in the foreign language and being able to identify words in the acoustic blur of normal conversational speech. As Wilga Rivers (1968: 135) remarked, emphasis in language teaching had hitherto been placed on students' production of the language, disregarding the fact that communication takes place between (at

least) two people. She suggested that the primary difficulty for a traveler in a foreign country was not the problem of making himself understood but of being unable to "understand what is being said to him and around him".

On the rare occasions when students were invited to listen to a tape to understand the content of what was said, they typically listened to a text that consisted of a narrative or discursive text read aloud slowly and distinctly by a native speaker. After listening to the tape, they were asked questions on the content. The questions, often as many as 10 or more, concerned information spaced at roughly equal intervals through the text, following the format widely used in 'teaching' the comprehension of the written language. Consider what these second language learners were being required to do: "treat all spoken language as primarily intended for transference of facts ... listen with a sustained level of attention, over several minutes to spoken language ... interpret *all of it* ... commit that interpretation to memory ... answer random, unmotivated questions on any of it" (Brown and Yule, 1983: 60). Sophisticated adult native speakers often had difficulty in recalling some of the trivial detail that such 'comprehension questions' addressed. For most second language learners, the experience was negative and demotivating.

The challenge since the 1960s has been to help students identify words in the stream of speech and to equip them with strategies to enable them to interpret the content of utterances in the relevant context of utterance and to work out what speakers mean by what they say.

Bottom-up Interpretation

It seems clear that structuralists were correct in claiming that being able to identify words in the stream of speech is fundamental to understanding what a speaker is saying. In some genres of speech, notably in relaxed conversation, where the focus is on the establishment or maintenance of social relationships, it may not be necessary to identify all the words that are spoken but, to participate meaningfully in the conversation, it is essential to identify at least those expressions that indicate the topic of the utterance and what is said about that topic. In primarily transactional genres, on the other hand, where the transfer of information will have some effect in the world, it may be essential to identify even the detail of those unstressed grammatical words that you can often afford to leave only vaguely guessed at in social conversation. When you are listening in your first language, you tend to be quite relaxed about how much you can afford not to fully interpret. In a second language, particularly in the testing situation of a classroom, it is hard not to panic if you realize that a series of unidentified words is rushing past your ears.

It is sometimes suggested that, in order to identify words in the stream of speech, it is necessary to be able to identify all the consonantal and vocalic oppositions that occur in the accent of the target language that students are being exposed to. This is a counsel of perfection. We should remember that in any accent of English, some of the oppositions found in other accents will not occur. Thus, standard American English does not distinguish between the words *balm* and *bomb*; young speakers of southern British English ('RP') do not distinguish between the words *paw*, *pore*, and *poor*; Scottish English does not distinguish between the words *cot* and *caught*, *cam* and *calm*, or *pull* and *pool*; Yorkshire English does not distinguish between the words *put* and *putt*; and London Cockney English does not distinguish between the words *sin* and *sing*, *thin* and *fin*, or *that* and *vat*. Yet, on the whole, speakers of different accents of English understand one another's speech well enough, even though in their own accent they do not make exactly the same set of phonological distinctions that their interlocutor makes. Second language learners are likely to encounter speakers from a range of different English accents and need to learn to identify the basic distinctions that are maintained in stressed syllables in all English accents, rather than spending much time on rare sets of oppositions that do not occur in most accents and which, even there, may carry only a low functional load. Whereas courses in pronunciation will normally be based on only a single native accent, courses in second language listening need to be much less constrained and to be relevant to a variety of major English accents.

There is obviously a significant difference between encountering words in the written and spoken forms of the language. In the written form, spaces between words unambiguously demarcate individual words. A major difficulty in interpreting the spoken form of a second language lies in determining where word boundaries occur. It is not always appreciated that crucial information needed in the task of segmenting the acoustic blur of the stream of speech lies not only in discriminating between phonological oppositions but also in identifying the phonologically conditioned variables that characterize particular consonants when they occur initially or finally in a word or stressed syllable. For historical reasons, much has been made in teaching English as a second language of the 'aspiration' (delayed voice onset time) that follows the articulation of a voiceless stop when it is initial in a stressed syllable. On the other hand,

the glottalization that precedes the articulation of the same set of phonemes in the coda of a syllable in most accents is typically ignored. Yet each feature is equally informative in identifying relevant parts of word structure (Brown, 1990: Chap. 2). Similarly much has been made in British ELT of the distinction between palatalized ('light') and velarized ('dark') /l/, without noting the generalization that the structure of the syllable in the RP accent is always more palatalized in the onset and more velarized in the coda of the syllable, a fact that affects the articulation of all consonants in these positions. The effect is most easily heard in sonorants and continuants where syllable-initial (onset) consonants will be heard as more palatalized, and hence higher in pitch, than syllable-final (coda) consonants. There are, of course, accents whose syllables are differently structured: the English of Glasgow has velarized consonants initially as well as finally, and Welsh English has palatalized consonants finally as well as initially.

Much more generalizable across accents than these palatal/velar subtleties is information about those phonotactic constraints that are helpful in identifying syllable and word boundaries, information that is sadly underexploited in the teaching of second language listening. For example, if an ESL listener hears a sequence /ml/ in the stream of speech, it is relevant to know that, since this cannot form an onset cluster in a syllable of English, it cannot mark the beginning of a word. The /l/ must be syllable initial, which means that the /m/ must be final in the preceding syllable; the significance of this fact is that where there are syllable boundaries, there are potential word boundaries (Cutler and Norris, 1988). An essential requirement is to learn to identify and to pay attention to the stressed syllable of words, since this is the syllable that is most reliably clearly articulated. In the stream of speech, a great deal of the phonological information that is available when words are pronounced slowly and clearly in citation form is routinely lost, particularly in unstressed syllables. Unstressed syllables are frequently elided, particularly when they occur as one of an unstressed sequence (for instance, in words such as *library, governor, extraordinary*). Processes of elision and assimilation take place across syllable boundaries and radically alter the familiar features of the citation form. Such processes occur densely in normal, informal speech whose relevance for learners is much greater now than it was pre-1970 since this type of speech is used in a much wider range of situations than it used to be. It is not only found in informal conversational contexts but is regularly heard on radio and television (even in news broadcasts, once models of slow, carefully articulated speech) and is standardly used in academic lectures and in public speaking more generally. (Harris (1994) and Shockey (2003) gave detailed accounts of these processes.)

I have suggested that a crucial component of second language listening is identifying words correctly. More to the point may be identifying the larger, prefabricated structures of which so much spoken language is constructed. Wray (2002) reviewed an array of studies that demonstrated the crucial significance of such structures, particularly in the early stages of learning a second language. It seems likely that many expressions are, initially at least, learned as unanalyzed chunks. Other expressions may be incorrectly analyzed (as in the case of the L2 learner of French who analyzed the spoken version of *chocolat* as *chaud cola*). In many cases, it may be that such expressions are stored and used quite effectively until eventually confrontation between spoken and written forms (or the utterance and the world) leads to a reanalysis. The acquisition of lexis, and of formulaic expressions in particular, is still the subject of extensive research.

Having identified (some of) the expressions in an utterance, the listener needs to order them into chunks that can be understood as syntactically structured and co-interpretable semantically. Just as the written language uses punctuation and layout to indicate the organization of discourse, there are various signals in speech, for instance, intonation, slowing down, and pausing, that indicate the boundaries of chunks of speech that need to be co-interpreted. In most accents of English, the beginning of a new sentential structure is typically indicated by being placed relatively high in the speaker's pitch range, and the rest of the structure is included within the overall contour that follows. The end of the structure is usually marked by being uttered at a lower level in the pitch range than the onset and is often followed by a pause. Internal sentential boundaries may be marked by shorter pauses and sometimes by variation in pitch height or direction (cf., Ladd, 1996).

Where spoken language differs dramatically from written language is in the scale of interruptions, modifications, and use of interpersonal markers in its production and in its reliance on the present context of utterance to constrain possible interpretations by the listener. Most speakers have had the experience of interrupting themselves, pausing, reconsidering, planning again, beginning to express themselves in one way, and then immediately modifying what they have just said. Unlike writers, they cannot undertake such operations secretly, without the interlocutor knowing. Second language learners unused to listening to spontaneous speech that has not been previously at least partially planned are in danger of having

their attention distracted from the message by material that is introduced as part of the planning process. Often the changes speakers make are marked by interpersonal and modal expressions such as *well, erm … I mean, so … you see … , if you get my meaning …, as far as I'm concerned …, I think …, I'm sure …,* phrases that disturb the smooth flow of a sentential structure at both a syntactic and an intonational level. A feature of spontaneous conversational speech that second language learners need to become accustomed to is how such universal features of spoken language are managed in the second language.

As speech plays such an important role in interpersonal relationships, its production is often modified by paralinguistic features that express the attitude of the speaker toward the listener and/or toward what is being said. English speakers who are being particularly polite to the interlocutor often speak higher in their voice range, relatively softly, and with a 'breathy' voice, whereas those who are being aggressive typically speak lower in their pitch range, more loudly, and with a 'harsher' voice quality. Speakers who are being sympathetic or kind speak low in their voice range, slowly, and typically with a 'creaky' voice. Whereas it seems plausible that basic human emotions such as fear, anger, or timidity are expressed similarly in all languages, it seems probable that attitudes that are more culturally conditioned are more likely to be variable in their expression across languages. Second language learners, at quite an early stage in their exposure to tapes and videos of L2 speakers interacting, might profitably pay attention to paralinguistic features of speech in order to identify whether speakers are agreeing or disagreeing with each other, being polite or aggressive, or friendly or unfriendly, long before they can understand the linguistic details of what is being said (Brown (1990), summarized in Rost (2002)).

Interpretation and Inference

Clark and Clark (1977: 45) drew a helpful distinction between 'constructing an interpretation' and 'utilizing an interpretation,' drawing attention to the fact that, in everyday life, we use language to get things done. In doing a crossword puzzle, we might construct an interpretation without putting the interpretation to further use but most speech is functional, either to interact with someone socially or to transfer or extract information. This implies that there is more to the interpretation of an utterance than simply identifying words, syntactic structures, and thin semantic meanings; we must infer what the speaker who produced the utterance intended to achieve by it. The term 'interpretation' reflects this process better than the term 'comprehension.' To have comprehended an utterance suggests a total, correct product now present in the listener's mind. For a listener who is trying to understand a decontextualized utterance in a language test, a translation equivalent of the thin semantic meaning may yield a judgment of 'correct' but, as Goffman (1981: 28) remarked, "the mental set required to make sense of these little orphans is that of someone with linguistic interests" rather than someone who is using language purposefully. It might be supposed that a total, correct product could be achieved in understanding short, banal utterances such as *what is the time?* But even such a familiar utterance may have been produced by the speaker primarily to bring about an awareness of the passage of time on the part of the listener, an intention that the listener may remain unaware of even after having produced an apparently appropriate translation. 'Interpretation' gives a better impression of the riskiness of the listener's effort to understand what the speaker means by producing the utterance and it gives no impression of finality – once constructed, an interpretation is not fixed and immutable but may subsequently be modified. It is because, in most genres, there can be no single 'correct' interpretation of what is said that some scholars question the possibility of measuring or assessing the degree of a student's 'spoken language comprehension' (issues discussed in Shohamy (1996); Spolsky (1994)).

To arrive at an interpretation, the listener needs to make inferences at many levels. To begin with, the listener may need to infer the identity of words not clearly heard but which would make sense of the utterance. Then, the effect of the immediate verbal context on the sense (meaning) of words must be taken into account. For instance, the word *red* prototypically denotes a strong, saturated red hue and the word *face* prototypically denotes the configuration of eyes, nose, mouth, and chin that would be represented in a child's drawing. However, once these words occur in the phrase *red face, red* must be interpreted as denoting a pinky, blotchy color, whereas *face* will draw attention particularly to the cheeks and perhaps the forehead but certainly not the eyes or mouth. The listener must infer which of a wide range of senses is appropriate in a given verbal context. For a second language listener, particularly one who has learned the foreign words in terms of one-word translation equivalents, extending the interpretation of a word well away from its central translational sense requires considerable confidence since it is obviously an operation fraught with risk (Færch and Kasper, 1986).

The issues of syntax, of combining words in one syntactic structure rather than another, and of the choice of syntactic structure having any effect on interpretation have been curiously neglected in cognitive models of comprehension. Most accounts of discourse meaning simply ignore the nature of the syntactic structures selected by the speaker and produce representations of discourse meaning consisting of a set of abstract semantic 'propositions' from which all specifically syntactic information has been expunged. A few writers have insisted on the significance of syntactic structure in determining how the semantic content of an utterance is understood (e.g., Brown, (1994); Levinson (2000)). Halliday (1978) pointed out the disruptive effect on the listener's presuppositional coherence of using inappropriate syntactic structures (consider which is the most appropriate radio commentary on a ceremony: *The sun's shining. The day's perfect.* versus *It's the sun that's shining and the day that's perfect*). Davison (1980) noted the effect on interpretation of using passive rather than active constructions in some circumstances, and Sanford and Moxey (1995) have drawn attention to the inadequacies of any account of interpretation based solely on propositional representation. It is far from clear why a language should develop different ways of expressing the same propositional content if using a different syntactic structure has absolutely no effect on meaning. Rather little experimental work has been conducted on the effect on interpretation of varying syntactic form but at least we should note that a competent listener would need to draw inferences when an unexpected syntactic structure is employed: compare the effect of *He certainly spoke to her* with *She was certainly spoken to by him*.

The Context of Utterance

It is a truism that spoken language typically relies heavily on context for its interpretation. There is a widespread view that speakers and listeners 'share' the context of utterance. Yet a moment's thought reminds us that speaker and listener can usually see each other's face and facial expression but not their own, and each of them has private interests, perceptions, judgments, and prejudices and brings to any interaction different hopes and expectations for its outcome. As Johnson-Laird (1983: 187). remarked, "the notion of the context overlooks the fact that an utterance generally has two contexts: one for the speaker and one for the listener. The differences between them are not merely contingent but. . .a crucial datum for communication". I shall consider three aspects of context from the point of view of the listener: external context of situation, social context, and textual/discoursal context. Each of these aspects of context interacts and overlaps with the others, more or less obviously in different genres (Brown, 1998).

The External Context

Utterances are produced in a particular place and at a particular time. Much of what is said will be assumed to be relevant to the place and time of utterance. If someone comes into a room, shivers, and says *It's cold*, the listener will understand that the comment applies to the current place and time – if not to the temperature within the room, then to the local external temperature. If I, in a temperate country, say in winter *It's warm today,* I mean that it is relatively warm for this locality at this time of year, not that it is as warm as it might be in August or in Singapore. If the speaker says *She's coming on Monday,* the listener will assume that the relevant 'Monday' will be the next one after the day of utterance. If the conversation is about 'the president,' 'the doctor,' or 'the school,' the listener should assume that it is the participants' current, local president, doctor, or school, if no contrary information is given. Conversations will, by default and in the absence of contradictory information, be assumed to be relevant to 'local' conditions, where 'local' can be interpreted as widely as *here* can be interpreted in *here in my hand, here in this room, here on this street, here in this town, here in this country*, and so on.

A concept of 'appropriate behavior,' which may differ in different cultures, will set limits on what it is appropriate to say and how it is appropriate to say it in particular places and at particular times. There are appropriate greetings for different times of day, for meeting, and for parting. There are some places, places of worship, for instance, where some topics or manners of speaking would be judged inappropriate. If I have a trivial message for you about the postponement of some distant future event, it would be inappropriate for me to come to speak to you about it in your hotel room at midnight, invading your personal space and possibly awakening you from sleep. If, in defiance of convention, I were to insist on speaking to you in such circumstances, you might well infer that I meant more than I was overtly expressing. The subtleties of contraventions, deliberate or intentional, of conventions governing types of utterance appropriate to particular external contexts are peculiarly difficult for second language learners to interpret with any confidence without extensive experience of the culture where the second language is used.

The Social Context

For the listener, the most significant figure in the social context is the speaker, and the significant relationship is that between speaker and listener. Whether the speaker is speaking to a group of listeners or shaping the utterance for just one listener, the speaker must make judgments about how far they will share what Clark called "communal lexicons" (1998: 60–87). Communal lexicons, Clark suggested, are built on such social features as shared nationality, education, occupation, hobbies, language, religion, age cohort, and gender. The more social features that the speaker and listener share, the more the speaker can rely on the listener being able to understand specialist vocabulary. Where speaker and listener share an occupation, suppose both are ship's engineers, even where the listener is a second language learner, they are likely to be able to negotiate the senses of technical terms with some confidence that each understands what the other is speaking of as long as the listener feels relaxed and is able to think clearly. However, when the speaker is the dominant participant in an interview that is communicatively stressful for the second language learner, for instance, when the learner is a junior doctor being interviewed for a job by a senior member of the profession, the ability of the listener to negotiate a shared understanding of a term may be curtailed, which may result in a breakdown of communication. For nervous students in examination conditions who are exposed to tapes of speakers with whom they share few, if any, of Clark's social features, only the most self-confident of students are likely to arrive at an adequate interpretation in the lottery of a speaker, or speakers, talking on a quite unpredictable topic that may be distant from any of the student's own interests. It will always be the case that a second language learner will have least difficulty in understanding language that the speaker is sympathetically shaping for that particular individual, taking account of the learner's current state of control of the second language and anticipated knowledge of the topic.

When listening to speakers from their own speech community, listeners will often make stereotypical judgments about the speaker on the basis of the speaker's self-presentation in terms of dress, hair, posture, and what the listener knows about the speaker's occupation. Such stereotypical judgments may influence the listener's interpretation of what the speaker says. If asked in the street what the time is by a smartly turned-out passer-by as opposed to one who gives the general impression of having just stumbled out of bed, different listeners may respond with different degrees of helpfulness in each case. If the listener hears *This is yet another example of hard work by the left* said by a left-wing politician, the listener will infer that the expression is used positively and appreciatively, but if the very same remark is uttered by a right-wing politician, the listener will infer that it is used negatively and critically. Second language listeners may feel uneasy about importing stereotypical knowledge of the world from their own culture into interpreting what is said in another language.

They may also fail to notice when they have not properly understood what someone says, as young L1 listeners have been shown to do in their own language (Markman, 1981) or blame themselves for not having understood when native speakers express the content of their message inadequately. Robinson (1981), working with native speakers of English, showed young children who hear elliptical or ambiguous messages from adults may be 'listener blamers,' who attribute their difficulties in understanding such messages to their own inadequacy, rather than 'speaker blamers,' who are capable of recognizing that the speaker has produced a confused and confusing utterance. If second language learners hear a native speaker assert something that the listeners cannot make sense of, like 'listener blamer' children they may believe that they have not interpreted what the speaker said correctly, simply because they are reluctant to question the authority of a native speaker.

The Context of Discourse

The discourse context is created by whatever the conversational participants are currently paying attention to and by what has already been said on the topic. It is the structure of what has already been established in the discourse context that allows the listener to determine what anaphoric expressions refer to and what, within the discourse world, new expressions refer to (Gernsbacher, 1990; Smith, 2003). How much the listener must carry in memory from the previous discourse varies with the type of genre at issue. In genres such as instructions on how to complete a task, where each instruction is followed by a pause while the listener completes that step in the task, there is minimal burden on memory. Instruction tasks may be made easier by limiting the number of parts or participants and making them clearly distinct from one another. Narrative genres, where an understanding of what is happening now depends on your understanding of what has happened earlier, are likely to impose a greater burden on memory. Again, narratives can be simplified if events are narrated in the order of occurrence ('*ordo naturalis*'), if the

number of participants is limited, and each participant is physically clearly distinguished from the other participants (Brown, 1995). The more complex the task, the more difficult it is to arrive at a secure interpretation, culminating in the problems of following abstract arguments in academic lectures (Chaudron, 1995).

Listening as 'Input' to Second Language Learning

When we consider the complexity of the demands made on the learner listening to a second language, it seems truly remarkable that such input can form the basis for learning the second language. Nevertheless, it is clear that to a greater or lesser extent, in different contexts of acquisition, some learners do successfully learn to control a second language to an impressive extent, largely from absorbing aspects of spoken input while simultaneously putting that input to use in constructing an interpretation of what a particular speaker intends to convey on a particular occasion of use. How this is achieved is the subject of extensive speculation in the second language acquisition literature (for a useful critical overview of the literature and an initial stab at a theoretical approach that distinguishes between the procedures of processing language for meaning and the processes of language learning, see Carroll (1999)). The most promising research thus far on this topic is that concerned with the acquisition of lexis, given spoken input (see, e.g., Ellis and Beaton (1993); Vidal (2003)).

Second Language Reading

E Bernhardt and M Kamil, Stanford University, Stanford, CA, USA

Introduction

Second language (L2) reading research is one of the older fields represented in the psychology literature (Bernhardt, 2003). In some sense, early L2 reading research might be characterized as something for curiosity seekers: a second language was used as a foil for a first. In other words, to examine one phenomenon (reading), scientists looked at a similar one from a different perspective (L2 reading) in order to verify universals in the process they were actually investigating. After this hothouse use of reading in second languages, the field of second language reading research lay dormant for many years. In reality, from World War I to the end of the Vietnam War, an interest in language (beyond grammar translation in the academic arena for literary use) was by and large focused on language for defense purposes or national interest (Moulton, 1963). An abrupt shift occurred in the mid–1970s, spurred by the massive global immigration brought about by war, economics, and technology. Language teaching became suddenly multipurposive, focused on preparing millions of nonnative speakers (of whatever language) to survive, work, and build lives in foreign cultures and countries in a manner in which previous generations could never have imagined. Efforts such as the European Unit Credit System (Trim, 1980), as well as the Oral Proficiency Movement in the United States (American Council on the Teaching of Foreign Languages, 1986) and the massive growth of professional organizations such as Teaching English to Speakers of Other Languages (TESOL) and the International Association of Applied Linguistics (AILA) are concrete reflections of the response to this global state of affairs. Most of the effort was expended on the development of oral skills with a survival-level reading and writing focus.

From the mid-1970s to 1995, reading in an L2 was by and large the domain of applied linguistics, and some significant work was conducted by applied linguists that led to both knowledge and theory development in the field. Volumes such as Alderson and Urquhart, 1984; Bernhardt, 1991; Carrell *et al.*, 1988; and Mackay *et al.*, 1979 populated the scene. The overwhelming portion of the work cited and collected in these volumes focused on adult readers, who more often than not came to the L2 reading process true to the concept of second. In other words, they had already acquired a native language and a native literacy.

The 1990s saw the awakening of education scholars to the concerns of second-generation immigrants. This second generation had frequently not been schooled in a home country (with, therefore, little or no native literacy) but rather needed to be schooled in a country where neither the language of schooling was spoken nor read in the home environment. This awakening brought about the widened expansion of interest in the field by literacy educators – i.e., scholars interested principally in mother-tongue literacy suddenly confronting the multilinguality that characterizes the overwhelming majority of classrooms as well as adult settings internationally. This expansion has brought welcome visibility to the area, as well as some communication difficulties across academic areas. Public and private efforts signifying an expanded interest in L2 literacy include *Teaching children to read,* the National Reading Panel Report (NICHD, 2000); the RAND Reading Study Group, *Reading for understanding,* RAND, 2002; National Literacy Panel for Language Minority Children and Youth Report, (forthcoming, 2005); as well as the *Handbook of reading research, volume II* (Barr *et al.*, 1991) and the *Handbook of reading research, volume 3* (Kamil, *et al.*, 2000). Scholars (Kern, 2000; Pennycook, 2001) also expanded their visions about L2 literacy, exploring the implications of a global technology that afforded immediate and essentially cost-free access to billions of written pages, as well as of the politics and social force of literacy.

This expanded interest and extended perspectives and objectives brought forth a set of academic and theoretical complexities surrounding L2 reading.

Second Language Reading

Introduction

Second language (L2) reading research is one of the older fields represented in the psychology literature (Bernhardt, 2003). In some sense, early L2 reading research might be characterized as something for curiosity seekers: a second language was used as a foil for a first. In other words, to examine one phenomenon (reading), scientists looked at a similar one from a different perspective (L2 reading) in order to verify universals in the process they were actually investigating. After this hothouse use of reading in second languages, the field of second language reading research lay dormant for many years. In reality, from World War I to the end of the Vietnam War, an interest in language (beyond grammar translation in the academic arena for literary use) was by and large focused on language for defense purposes or national interest (Moulton, 1963). An abrupt shift occurred in the mid–1970s, spurred by the massive global immigration brought about by war, economics, and technology. Language teaching became suddenly multipurposive, focused on preparing millions of nonnative speakers (of whatever language) to survive, work, and build lives in foreign cultures and countries in a manner in which previous generations could never have imagined. Efforts such as the European Unit Credit System (Trim, 1980), as well as the Oral Proficiency Movement in the United States (American Council on the Teaching of Foreign Languages, 1986) and the massive growth of professional organizations such as Teaching English to Speakers of Other Languages (TESOL) and the International Association of Applied Linguistics (AILA) are concrete reflections of the response to this global state of affairs. Most of the effort was expended on the development of oral skills with a survival-level reading and writing focus.

From the mid-1970s to 1995, reading in an L2 was by and large the domain of applied linguistics, and some significant work was conducted by applied linguists that led to both knowledge and theory development in the field. Volumes such as Alderson and Urquhart, 1984; Bernhardt, 1991; Carrell *et al.*, 1988; and Mackay *et al.*, 1979 populated the scene. The overwhelming portion of the work cited and collected in these volumes focused on adult readers, who more often than not came to the L2 reading process true to the concept of second. In other words, they had already acquired a native language and a native literacy.

The 1990s saw the awakening of education scholars to the concerns of second-generation immigrants. This second generation had frequently not been schooled in a home country (with, therefore, little or no native literacy) but rather needed to be schooled in a country where neither the language of schooling was spoken nor read in the home environment. This awakening brought about the widened expansion of interest in the field by literacy educators – i.e., scholars interested principally in mother-tongue literacy suddenly confronting the multilinguality that characterizes the overwhelming majority of classrooms as well as adult settings internationally. This expansion has brought welcome visibility to the area, as well as some communication difficulties across academic areas. Public and private efforts signifying an expanded interest in L2 literacy include *Teaching children to read,* the National Reading Panel Report (NICHD, 2000); the RAND Reading Study Group, *Reading for understanding,* RAND, 2002; National Literacy Panel for Language Minority Children and Youth Report, (forthcoming, 2005); as well as the *Handbook of reading research, volume II* (Barr *et al.*, 1991) and the *Handbook of reading research, volume 3* (Kamil, *et al.*, 2000). Scholars (Kern, 2000; Pennycook, 2001) also expanded their visions about L2 literacy, exploring the implications of a global technology that afforded immediate and essentially cost-free access to billions of written pages, as well as of the politics and social force of literacy.

This expanded interest and extended perspectives and objectives brought forth a set of academic and theoretical complexities surrounding L2 reading.

These complexities can be characterized, first, by the search for a model of L2 reading that can accommodate a range of languages, developmental trajectories, and social/affective dimensions. Second, the expanded interest has brought forth a renewed perspective on the concept of transfer – what is transferred between languages when a literate or nonliterate first language (L1) reader attempts to understand in a second. Third, expanded views also pushed the field of L2 reading into a greater recognition of the import of the social context – whether that social context is the home background of a young reader, or that of an adult coping with abstract content material on the internet. These three areas form the organizational structure for the bulk of this article.

Current State of Theory

Three formally stated models of the L2 reading process have appeared in the literature. The first model, Coady (1979), was deliberately psycholinguistic in nature and isolates the variables of "conceptual abilities, background knowledge, and process strategies" (Coady, 1979: 6) with process strategies including word-level processes that are graphemic/morphemic in nature; lexical and syntactic knowledge; learning strategies; and affect. Coady plotted the processing strategies over time with higher-level processes such as the use of lexicon and context, becoming increasingly more important over time with word-level skills diminishing in importance. Within the statement of the model, no data were provided. Bernhardt (1991) influenced by Coady's positing of the process put the model to test, citing data from comprehension protocol studies of readers of French, German (German, Standard), and Spanish. Protocol data were by and large consistent with Coady's positing with the exception of the importance of syntax, which Coady posited as neutralizing throughout the L2 reading process, and which Bernhardt concluded became increasingly more significant in causing errors in comprehension before leveling off. A decade of research later, Bernhardt (2000) re-examined reading performances by examining studies that focused on readers comprehending equivalent texts in two languages. Such an examination – one that accounts for the impact of an L1 literacy on a second – provided a third installment of a model of L2 reading.

This third installment reviewed data across a number of languages and captured three specific areas in which there is consistency in research findings of readers of second languages: first, the impact of language (L2) knowledge on the L2 comprehension process; second, the contribution of literacy (L1) knowledge to understanding in a second language; and third, the acknowledgement that 50% of the L2 reading process remains uninterpreted. The first two elements call for a re-interpretation of the debate over the existence and criticality of a language and literacy threshold that characterized the research of the 1980s. The final element, 'the unknown 50%,' points toward the deficits in a theory based on a narrowly defined group of readers (principally adults) and an even narrower conceptualization of the context against which reading is learned and used. Failure to consider these critical variables exposes significant gaps in the understanding of L2 reading.

Revisiting L1/L2 Relationships: the Transfer of Literacy and Language Knowledge

In language learning, the most commonly cited definition of transfer came from Odlin (1989):

> Transfer is the influence resulting from similarities and differences between the target language and any other language that has been previously (and perhaps imperfectly) acquired (1989: 2).

The most obvious characteristic of this definition is its similarity to the psychological conception of transfer based on identical elements. Language transfer describes the phenomenon of influence between the existing L1 knowledge and the development of L2. Transfer can take both a positive, facilitating manifestation and a negative manifestation, which is marked by interference errors or overuse of certain forms. According to Ellis (1994), transfer was "historically speaking . . . the first factor to receive serious attention" (Ellis, 1994: 299). As transfer is a cross-linguistic phenomenon, the contrastive analysis hypothesis (CAH) assumed that structural differences between two languages represented difficulties and were a predictable error source, whereas structural similarities facilitated the development of the L2. The validity of this hypothesis has been both overestimated and underestimated in the past (Ellis, 1994: 306–312). Nevertheless, today it is not possible to "dismiss the evidence of transfer effects in bilinguals as irrelevant to L2 acquisition" (Ellis, 1994: 310).

Cummins formulated his well-known CALP/BICS distinction against the backdrop of transferability. He differentiates between linguistic skills and conceptual/academic skills. The language interdependence principle argues that transfers of universal, conceptual aspects of language proficiency occur automatically, after linguistic surface features of the L2 are acquired. The acquisition of the linguistic skills

necessary for the communication in the L2 initiates "[the] transfer of cognitive/academic or literacy-related skills across languages" (Cummins, 1984: 143). However, Cummins's threshold hypothesis put this strong claim into perspective. The threshold hypothesis argued that the transfer of cognitive skills from L1 to L2 only operates after the learner's performance of linguistic skills in the L2 has reached a certain threshold (Cummins, 1984: 106–107).

Cummins's conceptions have had a powerful effect on research in second language reading. They are, however, largely untestable, even though they seem to suggest very specific types of predictions. First, most of the data on which these formulations were based were from language acquisition studies, not literacy. They have been brought into the literacy area without adequate grounding in empirical research in reading and writing. Second, the two formulations make contrary predictions. Either L1 and L2 are interdependent or L2 operates only after some threshold. These are what are often referred to as under-specified theoretical perspectives. Neither formulation is sufficiently precise as to exclude the other. Finally, it is not clear how one defines a threshold. Until that is done, these two formulations are interesting heuristics, but not scientifically useful.

Recent thinking about transfer has shown that the situation is somewhat less clear when complex learning tasks are involved. The general findings are typically that individuals do not spontaneously transfer from one problem to the next. Bransford and Schwartz (1999) differentiated the conditions under which transfer has been studied. They described traditional studies of transfer as involving what they termed "sequestered problem solving" (1999: 61). In this assessment of transfer, individuals are given new problems to solve, but are denied resources to which they might have access in the initial learning. Bransford and Schwartz noted that the theory undergirding this conception is one that views transfer in terms of the direct applicability of prior learning in new contexts.

Bransford and Schwartz proposed an alternative to the traditional formulation by emphasizing what they term "preparation for future learning" (PFL) (Bransford and Schwartz, 1999: 61). In short, the notion here is that transfer is best viewed as the ability to learn in knowledge-rich environments. In an extensive review of the research, combined with new evidence, they show that some of the evidence of positive transfer was obscured by the conditions under which transfer was assessed. When learning was assessed under richer conditions, it became clear that learning was more efficient when learners had appropriate prior experiences. That is, learners could have experiences which did not necessarily relate directly to the task (in terms of identical elements) but which provided insights into what was needed in new situations. This has important implications for language transfer.

Transferring Knowledge About Language Elements

At first glance, the concept of transfer from L1 to L2 is simple: similar elements exist between and among all languages, and some languages are more similar to each other than they are to others. Basic features such as phonetic components and orthography form important loci of similarities and differences. Absent from much of the conceptual work on transfer in the L2 research literature is a perspective related to learning. The literate status of learners is key: learners are either literate or not in L1. When literate L1 learners enter an L2 literacy-learning environment, the important question is whether they have an easier time learning to read in L2. If they do, there is positive transfer. If they find it more difficult to learn to read than L1 learners, there is negative transfer. For learners who are not literate in L1, there are two questions. The first is whether or not such learners learn to read in ways that are the same or different from learners in an L1 context. An ancillary question is whether the transfer from L1 literacy to L2 literacy is sufficiently great to warrant teaching students L1 literacy *prior* to beginning L2 literacy instruction. One final issue that is not readily apparent is the tension between transfer of ability and transfer of knowledge; i.e., whether or not knowledge (content) is represented differently in different languages. It would seem that the reason for this tension is that content issues are not well represented even in the L1 reading literature. Another reason may be the implicit assumption that what the individual knows about the world is simply available, regardless of the language in which it is expressed.

Studies of metalinguistic awareness provide some insights into transferability by trying to separate the effects of literacy from those of bilingualism on specific measures of metalinguistic awareness. Carlisle *et al.* (1996) investigated the relationship among developing metalinguistic capabilities, English language proficiency, and literacy for Hispanic high school students who qualify for bilingual educational programs. High school students receiving services from the bilingual education program, all native speakers of Spanish, were given several tests such as an English and a bilingual grammar test and a definitions test. Overall, students had relatively low levels of English literacy achievement and metalinguistic capabilities

across the grade levels. The quality of their formal definitions was related to their reading and to their non-verbal problem solving, but not to their English oral language proficiency. There was a significant correlation between the formal definitional quality and the performance on the English reading test, and also between the formal definitional quality and the nonverbal cognitive development test, suggesting transfer across languages. Additional work with primary school children, indicates that performance on a definitions task is explained by word knowledge in the language of the task, and that degree of bilingualism is not significant when level of vocabulary knowledge is considered. Generally speaking, it appears that metalinguistic awareness transfers and may even be heightened by learning to read in a second language.

Further work examines the relationships between and among other reading variables. Gholamain and Geva (1999) examined the parallel development of reading in English and Persian. They suggest that there are common underlying cognitive and linguistic factors, such as working memory or rapid letter naming. They also found that acquisition of the principle of grapheme-phoneme correspondence rules in Persian did not require differential proficiency in Persian. This research is suggestive of the transfer of some phonological abilities, if not the exact graphophonemic rules. Additional research shows that phonological processing is transferred across Spanish-speaking first-grade children learning English (Cisero and Royer, 1995). English oral language proficiency predicted English and Spanish word reading, but Spanish proficiency did not predict English word reading. The general conclusion is that there is transfer of phonological processing skills across languages. It is also important to note that the set of languages studied in this arena is widely varied, including both Roman and non-Roman orthographies.

Transferring Language Elements: Grammar and Vocabulary

One of the earliest-researched variables in the reading and psychological literature about reading is morphosyntax. Ironically, this critical feature of text (how words in strings relate to each other) is, generally speaking, ignored in contemporary literacy research. This may well be because there is scant research found in the English language literature that addresses the impact of either morphology or word order on text comprehension. Indeed, the English language is, syntactically speaking, relatively inflexible. Word order is by and large SVO, and there is relatively little variance between spoken and written syntax. In a monolingual, English-speaking context, therefore, syntax may be an inconsequential variable. Readers and listeners are attuned to a predictable, strict word order.

Early studies using an eye-movement methodology, examined native; nonnative, highly fluent; and nonnative, nonfluent readers reading the same texts in German. Native Germans read in a relatively linear fashion; nonnative nonfluent readers put German into their own syntactic rules for word placement; and nonnative yet fluent readers were somewhere in the middle – not mentally rearranging German words, but certainly spending more time in areas of the text that both natives and the nonfluents were simply skimming (Bernhardt, 1991). Native readers of German also directly fixated endings of words, in contrast to readers of English who moved from content word to content word indeed seeing function words, but rarely spending more than 100 milliseconds on them.

In a parallel vein, qualitative data generated through recall were based on readers of various levels reading and recalling authentic texts in German, French, and Spanish. In these studies, readers would reveal a fairly discombobulated English syntax in their recalls, often failing to recognize which word an adverb was actually modifying, or who was doing what to whom. Support for the belief that syntax, or the way in which words relate to each other, is a key variable in predicting L2 reading comprehension is derived from the work of Odlin (1989) and Kern (2000). Evidence within L2 contexts predicts that the impact on the comprehension process of readers moving between predictable and unpredictable word order, for example, is significant. Languages such as German, Russian, or French exhibit degrees of flexibility in word order and, consequently, readers cannot merely rely on word meaning to comprehend, but must understand the signaling relationships between and among words (Kern, 2000). Odlin (1989) notes that L2 learners from flexible-word-order languages have higher numbers of production error rates when learning rigid-word-order languages. Odlin further hypothesized that learners from rigid word order languages have higher error rates in the receptive language skills, namely reading and listening. Few recent L2 studies examining the reading of either children or adults have examined morphosyntax extensively. While the finding that at least 30% of the L2 reading process can be predicted on the basis of language knowledge is consistent, few studies have examined the components of language knowledge. The exception is Brisbois (1995), who managed to decompose the 30% variance into 27% vocabulary and 3% grammatical knowledge.

Vocabulary knowledge is crucial to reading comprehension in L1 (NICHD, 2000). It has long been the case that L1 researchers believed that comprehension was composed of two skills: word knowledge, and reasoning. There is evidence that this applies equally to reading in L2 (Saville-Troike, 1984), although the research is neither as abundant nor as methodologically rigorous as it should be to reach unambiguous conclusions. Verhoeven (2000) found that for first- and second-grade children, vocabulary knowledge had a greater impact on L2 learners than on L1 learners. For speakers of Urdu, Mumtaz and Humphreys (2002) found that students with high levels of vocabulary knowledge and phonological awareness in Urdu were more likely to perform well on English reading tasks. It may be that vocabulary knowledge leverages the ability of readers to make use of the alphabetic principle by recognizing words more efficiently.

For example, for Spanish L1 students in first grade, reading and phonological processing appear to be related both within and across languages. Three factors seem to relate to proficiency: reading, oral language, and phonological processing. In addition, English vocabulary and reading also seem to be related, suggesting that vocabulary supports processing in beginning readers. This might also be interpreted as providing the same kind of leverage hypothesized above. Garcia (1991) found that unfamiliar English vocabulary was the major linguistic factor that adversely affected the reading test performance of fifth- and sixth-grade Spanish-speaking students. In the case of bilinguals, how conceptual and word knowledge (vocabulary) is represented in memory is still not well understood. Similarly, Nagy *et al.* (1997) explored the effects of Spanish-English bilinguals' L1 knowledge of syntax on their ability to guess the meanings of new words in English (L2). The importance of this study of seventh- and eighth-grade students is that it disentangled the contribution of language proficiency from knowledge of syntactic differences between L1 and L2. Evidence of transfer was found in that participants used their L1 syntactic knowledge to make guesses about the meaning of words in L2 contexts.

Some evidence suggests that vocabulary knowledge does not transfer very well for kindergarten students learning dissimilar languages such as Turkish and Dutch (Verhoeven, 1994). Yet, for older Spanish-speaking children (4–6) reading in English, Durgunoglu *et al.* (1993) found that knowledge of cognates, i.e., words with common ancestral roots with similar forms and meanings, can facilitate comprehension in the second language. Investigating the relationship between Spanish vocabulary knowledge, ability to recognize cognates, and English reading comprehension, indicated a significant transfer between knowledge of Spanish vocabulary and performance on the English comprehension task. More importantly, Spanish vocabulary knowledge and recognition of cognates interacted. Performance on the English multiple-choice items was highest in those cases where the student both knew the word in Spanish and recognized the English cognate.

The few studies on vocabulary transfer suggest that instruction should include the teaching of bilingual strategies for resolving unknown vocabulary, such as the use of translation, cognate searching, and word substitution (Nagy *et al.*, 1993; Garcia, 1998). Nagy *et al.* (1993) showed that the students underutilized their knowledge of cognates, indicating the potential for a cognate recognition strategy as a means for enhancing Spanish-speaking children's reading comprehension in English. For readers from noncognate languages, little research exists and yet is critical toward understanding the process of second language reading in its entirety.

An emphasis on cognate searching is not a trivial strategy for many L2 readers struggling with comprehension. Cognates in Spanish and English, most of which are taken from Latin and Greek, often "look alike" and sound alike (Nash, 1997). The entire set of these shared cognates is estimated to be between 10 000 to 15 000 words, which accounts for one-third to one-half of "the average educated person's active vocabulary ... with additional cognates in a person's passive vocabulary, that is, specialized, literary, and obsolete words" (Nash, 1997). If the transfer of the knowledge of these words is accomplished, an L1 learner has a head start to learning a second language. The caveat here is that there is a wide variation in the shared cognates between languages. Languages that do not share common linguistic roots will have few, if any, cognates. Consequently, the utility of cognate searching as a strategy is dependent on the relationship between L1 and L2.

Studies about how adult L2 learners learn new words or compensate for unknown words fall into three categories. The first category includes studies that investigate the role of traditional vocabulary lists and dictionaries. Davis (1989) found that vocabulary lists provided to learners prior to reading enhanced comprehension. No followup to how many of the words were actually acquired was conducted, although Hulstijn *et al.* (1996) provided some evidence in this regard. They found that Dutch learners of French who were most able to acquire incidental vocabulary through reading had access to marginal glosses. Generally speaking, most investigations find positive effects on vocabulary learning from the use of dictionaries, with some reported skepticism, however,

about the direct instruction of words with the use of dictionaries.

A second arena of investigation examines the polar opposite: the acquisition of words with no external support. Most of the studies in this area argue that the contexts surrounding words play critical roles in the acquisition of words meaning. They therefore cast doubt on the genuine utility of dictionaries that tend to provide a one-word meaning or translation. Some evidence exists that extensive reading fosters vocabulary acquisition, yet Laufer (2003) expressed skepticism that significant numbers of L2 words can be acquired through extensive reading. Other studies, e.g., Pulido (2003), noted that examining either dictionaries or extensive reading *per se* were not fruitful lines of inquiry without also considering the role of L2 proficiency, as well as the nature of the first language and culture in understanding the meanings of new L2 words.

A third area of investigation is comprised of studies that consider the contexts in which learners will use word-learning aids, and how they go about intentionally learning new words. The importance of repetition in new L2 word learning seems to be clear. Hulstijn (1993), whose subjects were 82 Dutch learners of English, examined the conditions under which learners employ word-learning strategies. Hulstijn found effects for both general literacy knowledge and for task. In others words, the greater the literacy level, the lower the chances of looking up words. Further, the comprehension task also determined the extent to which learners confronted individual words. When the task was a general summary, learners tended to look up fewer words than when they knew in advance that they would have to answer an explicit question.

Contextual Variables

The third complexity introduced into L2 reading research over the past years is the growing acknowledgement of the importance of contextual factors in literacy acquisition. These are factors that mediate and mold comprehension well beyond morphological, syntactic, or vocabulary knowledge in any language. For young children, the most important contextual factors for early reading is language and literacy activities in the home. For the acquisition of L2 literacy, there are differential effects of oral language and literacy activities. In an analysis of the literature, Goldenberg (2004) concluded that home literacy experiences in either L1 or L2 were, in general, positively associated with literacy attainment in either L1 or L2. By contrast, home oral language effects on literacy attainment were more differentiated. Home L1 oral language appears to be unrelated or negatively related to L2 literacy, although it has positive effects on L1 literacy. Home L2 oral language appears to have positive effects on L2 literacy acquisition. The results appear to be mixed when it comes to the effect of home L2 oral language on L1 literacy acquisition.

One possible explanation for this phenomenon is that oral language mediates early reading acquisition. Given the practice a child might have in either L1 or L2 is a trade-off. The more one language is used, the less the other will be. For literacy, the presence of any literate activity may serve as a model in either language. These results implicate the importance of the home environment variable in learning to read, either in L1 or L2. Other context variables, outside of SES, did not prove to be powerful. There is little evidence that language prestige and immigration circumstances influence literacy outcomes. Nor is there any evidence that discourse and interactional differences influence literacy outcomes.

Research on adult readers of second languages has examined an array of variables from gender and topic interest through instruction to the impact of particular text types (principally expository versus literary) on the impact of the acquisition of reading in second languages. Most of this research carries with it significant findings regarding one variable or another. The bulk of the work must be regarded with skepticism, however, because of the shallow context against which it has been conducted. Most studies isolate a variable without considering either the transfer of knowledge or linguistic forms that clearly interact in the process of second language reading. The converse of this research paradigm is that presented under the rubric of *critical*. Pennycook (2001) noted that "a great deal of work in critical literacy has shown how the significant issues for literacy are not so much how the brain deals with text but how literacy is related to its context" (2001: 77). Pennycook argued for an expanded vision of the elements entailed in a highly charged concept such as literacy. Indeed an expanded view de-emphasizes language elements and importantly emphasizes power relationships in the use of those language elements and points toward how adult L2 readers act on the content of what they are asked to read and understand.

Conclusion

The future of L2 reading research lies in theory development that integrates the knowledge provided by the areas noted above. A good theory attempts to capture a knowledge of the present and to point researchers and practitioners into important and targeted conceptualizations for the future. No such

theory currently exists. Present models either ignore young, developing readers learning and reading in two languages, or ignore developed L1 readers reading in L2. Any theory must try to account for the array of variables that characterizes L2 readers. In addition, present models oversimplify the transfer of both literacy knowledge and language knowledge to the L2 comprehension process. Transfer can be both negative and positive; it can interfere or facilitate; it can be deep or shallow. Models of the L2 reading process must be able to reflect the diversity and complexity of moving between and among languages of very different manifestations as well as different literacy levels. Finally, theory development must acknowledge the backdrop against which L2 readers learn to read in a second language and how they go about using the knowledge they acquire through reading. This is a tall order for theory development.

In order for more adequate theory development to occur, research designs will need to reflect the complexity of L2 reading. Stating the literacy levels of subjects in studies; their age and schooling levels; the linguistic nature of the two languages involved, including the level of cognate overlap; the linguistic knowledge that subjects have of the second language; as well as the sociocultural relationship between two languages will be critical in offering substantial and credible data. Examining the multivariate process of reading in an L2 through univariate lenses will not help the field progress. Variables within the L2 reading process are in contingent relationships with each other. The future lies in research designs that mirror these relationships.

Second Language Speaking

Introduction

The productive skill of speaking in a second language has received attention only in relatively recent times. Bygate (2001) noted three reasons for this. First, many of the dominant approaches to language teaching (notably the grammar-translation approach) do not give any priority to the promotion of oral communication. Second, only since the mid-1970s has there been widespread availability of good recording media to facilitate the in-depth study of recorded natural speech and to allow for the use of spoken material in classrooms. Third, many of the approaches to language teaching, other than grammar translation, did use oral communication in the target language as a central medium for teaching (for example, the direct method, the audiolingual approach); however, ironically, speaking as a skill largely focused only on pronunciation. In the case of audiolingualism, the importance of speaking was highlighted in its input-before-output sequence: listening–speaking–reading–writing. This behaviorist

Introduction

The productive skill of speaking in a second language has received attention only in relatively recent times. Bygate (2001) noted three reasons for this. First, many of the dominant approaches to language teaching (notably the grammar-translation approach) do not give any priority to the promotion of oral communication. Second, only since the mid-1970s has there been widespread availability of good recording media to facilitate the in-depth study of recorded natural speech and to allow for the use of spoken material in classrooms. Third, many of the approaches to language teaching, other than grammar translation, did use oral communication in the target language as a central medium for teaching (for example, the direct method, the audiolingual approach); however, ironically, speaking as a skill largely focused only on pronunciation. In the case of audiolingualism, the importance of speaking was highlighted in its input-before-output sequence: listening–speaking–reading–writing. This behaviorist

view of language perceived speaking as a series of habits (in reality, structures) that could be broken down and learned by "no more than engineering the repeated oral production of structures in the target language" (Bygate, 2001: 15). Since the 1970s, other influences have changed the way we view second language speaking, most notably cognitive and sociolinguistic theories and the rise to prominence of spoken corpora.

Models and Descriptions of Second Language Speaking

Theoretical Models for Understanding Second Language Speaking

Concerted study of second language acquisition (SLA) has been under way since the late 1960s. A number of early SLA studies looked at the interactional aspects of speaking that were relevant to language learning. Simultaneously, and often independently, models of spoken language description, such as ethnography of speaking, conversation analysis (CA), interactional sociolinguistics (IS), discourse analysis (DA), and critical discourse analysis, have been evolving. Boxer (2004) noted that although some recent research in SLA has begun to glean insights from the various approaches to the analysis of spoken discourse, there is much more that could be studied to illuminate the theoretical and practical aspects of SLA. As she noted by studying how language users employ their language in a variety of contexts, with various types of interlocutors, and on a variety of topics, students, teachers, and scholars can create curricula, materials, and assessment instruments based on something more substantial than the intuition of mother tongue users. Boxer (2004: 8) identified three theoretical models that offer 'fairly compatible insights' into the processes involved in the development of spoken language ability in both first and second/additional languages. These are: (1) Language Identity, (2) Language Socialization, and (3) Sociocultural Theory.

The Language Identity model focuses on the impact of taking on an additional language in terms of an individual's identity (see Pavlenko and Lantolf, 2000). For those learning a language, the primary resource, as Boxer (2004: 9) noted, is "social and interactional, involving face-to-face spoken discourse." Pavlenko and Lantolf (2000) looked at the process that immigrants go through when they are faced with learning a new language. They either choose to appropriate or reject linguistic and cultural aspects of the new language and its culture that can potentially change one's sense of self. Within the same paradigm, but focusing on the cumulative effect of interaction, relational identities are said to build up over time, and successful interactions for language learners lead to further interaction and in turn promote more opportunities for language development (see Boxer and Cortes-Conde, 2000).

Language Socialization offers a framework for the study of second language speaking in which language is viewed as the symbolic means by which humans appropriate knowledge of norms and rules of verbal and nonverbal behavior in particular speech communities. Becoming a competent member of any speech community means taking on appropriate behaviors of the community. Most of the research in this area focuses on the first and second language development of children in particular speech communities and the role of parents and teachers who make explicit what ought to be said and done (see Boxer, 2004). SLA studies that draw on a Language Socialization model focus mostly on socialization practices in the classroom from the perspective of a community of practice rather than in a speech community. Socialization practices of such communities are reflected in the classroom discourse and interaction of second language classes in which talented teachers take on the role of socializing agent, much in the same way as adults take on this role with children in first language development.

The third and most influential model that Boxer (2004) identified as appropriate for the study of the processes involved in the development of second language speaking is Sociocultural Theory (SCT). This movement, springing mainly from the work of Lantolf and his associates, draws on the theories of Russian psychologist Lev Vygotsky (see Vygotsky, 1978, posthumously published). Vygotsky's philosophy supports the view that the acquisition of language (first and additional) is a sociocultural process linking the social/interactional with the cognitive. Boxer (2004) noted that contrary to Language Identity and Language Socialization models, SCT specifically connects the role of language as a mediating tool between social interaction and the development of higher-order mental processes. This theory proposes that mental functioning such as memory, attention, perception, planning, learning, and development come under the voluntary control of individuals as they internalize culturally constructed artifacts, which include all culturally organized forms of communication (Lantolf, 2000). Social relationships are transformed into psychological processes by individuals as a means of mediating their own mental activity.

Examination of Vygotsky's work (e.g., Lantolf, 2000) generated debate among applied linguists on

how such a perspective might feed into the teaching and learning of second language speaking. Two central notions of the Vygotskian paradigm are relevant here: the notion of scaffolding and that of the zone of proximal development (ZPD). Scaffolding is the cognitive support provided by an adult or other guiding person to a child or learner. Scaffolding occurs in dialogue, so that the child/learner can make sense of challenging tasks. The ZPD is the distance between where the child/learner is developmentally and what he or she can potentially achieve in interaction with adults or more capable peers (Vygotsky, 1978: 86). The concept of scaffolding refers to a situation where the interlocutor possessing the expertise guides the novice through a series of interactions in which the expert gradually cedes control as the novice takes on increasing responsibility and becomes more adept (Hall, 1997). This happens through the various configurations of social interaction, and as the process goes on, that which began as an intermental, socially mediated activity becomes an intramental, cognitive development process. In contrast to most traditional SLA perspectives, SCT views the learner not as a deficient version of the idealized monolingual expert, but as an active and creative participant in a "sociocognitively complex task" (Hall, 1997: 303). Instructors (or peers) and their pupils cocreate the arena for development; it is not preordained and has no locksteps or limits. Meaning is created through dialogue (including dialogue with the self, as may be evidenced in 'private speech') while the participants are engaged in activity. Ohta (2001) conducted a longitudinal case study of the private speech of seven adults learning Japanese in their foreign language classroom at the University of Washington in 1996 and 1997. She used the private speech of the learners to access what was actually going on in the mind of a learner while learning a second language. She defined private speech as "oral language uttered not for communicative interaction with another, but for dialogue with the self" (Ohta, 2001: 14), that is, an intermediary between social and inner speech. Ohta claimed that private speech has particular potential as a data source because it provides a window into the mind as it works on the cognitive, intimately social interactive problems presented by learning language, arguing that the paramount understanding is that private speech is not only a frequent feature of L2 classroom activity, but evidences SLA in process. She compared private speech to a moving picture of language acquisition in process.

In terms of the effectiveness of the Vygotskian approach in promoting second language speaking, Machado (2000) showed how peer-to-peer mutual help during the preparation stages of speaking tasks in the classroom (for example, negotiating interpretations of the tasks and the wording of meanings) can be directly reflected in the performance phases of the same tasks, suggesting that internalization of scaffolding has taken place. This supports the view that peer-to-peer scaffolding may be just as important as expert–novice scaffolding in the improvement of spoken performance. Ko *et al.* (2003) also took this line and sought to explicate what constitutes good, effective negotiation-of-meaning interactions in classroom tasks (see also Kasper, 2001). The contributions to such tasks made by the teacher may be enhanced by contributions from peers during the negotiation phase between separate performances of the same task, again suggesting the central role played by scaffolding in promoting and improving second language speaking. As a caveat to the general optimism toward Vygotskian approaches to second language speaking, Kinginger (2002) warned against the uncritical importing of concepts such as scaffolding and the ZPD in ways that do no more than justify unreformed current practices (e.g., the input–output hypotheses, all and any types of pair- and group-work tasks, teacher feedback moves), rather than genuinely reexamining the part played by social interaction in language development. In this respect, the work of Swain and associates (for example Swain and Lapkin, 2000) presented the ZPD as an open-ended arena for unplanned development and unpredictable events, and not as a fixed discourse based on input and output or the tightly circumscribed sequences of teacher–learner exchanges. Hughes (2002) also repeatedly stressed the need for proper social and cultural contextualization of second language speaking activities, and there certainly seems to be a growing awareness that second language speaking in pedagogical settings should not take place in a vacuum, sealed off from the social and cultural life of the learner.

Recent research has investigated the design and implementation of speaking tasks within cognitive frameworks, focusing principally on fluency, complexity, and accuracy of production (Bygate, 2001 provided an overview of the evolution of such research). Robinson (2001) has argued that stepping up the cognitive complexity of speaking tasks affects production, with a greater lexical repertoire on show in more complex versions and greater fluency evidenced in simpler versions of the task. Yuan and Ellis (2003) looked at the positive impact of pretask planning on learners' spoken production, especially with regard to fluency and complexity, even though it was not obvious that accuracy benefited. Yuan and Ellis also examined situations where learners were given unlimited time to formulate and monitor their

speech while performing; such planning seemed to positively influence accuracy and grammatical complexity. Research has also looked at repetition and recycling in speaking tasks and their contribution to the integration over time of fluency, complexity, and accuracy of spoken production (Bygate, 2001). Additionally, the role of the teacher in relation to task design and implementation and the teacher's ability to provide scaffolding to underpin the development of competence in speaking has become a focus.

Analytical Approaches for Understanding Second Language Speaking

Describing spoken language was a very difficult task before the widespread availability of audio recording equipment. Not surprisingly therefore, the past 40 years have seen a proliferation of studies and emergent methodologies in this area. Most relevant to the study of foreign language speaking have been conversation analysis (CA), Discourse Analysis (DA), and Interactional Sociolinguistics (IS). Though these analytical approaches differ, they all focus on empirical data and are concerned with turn-by-turn analysis of spoken interactions across many contexts of use. They have largely been used to describe first language interactions but many illuminating studies of foreign language speaking have also been carried out.

CA studies the social organization of conversation, or talk-in-interaction, by a detailed 'bottom-up' inspection of audio (and sometimes video) recordings and transcriptions. Core to its inductive analysis of the structure of conversations are the following areas: (1) the rules and systematicity governing turn-taking; (2) how speaker turns can be related to each other in sequence and might be said to go together as adjacency pairs (for example, complaint + denial A: *You left the light on*. B: *It wasn't me*.); (3) how turns are organized sequentially in context at any given point in an interaction and the systematicity of these sequences of utterances; (4) how seemingly minor changes in placement within utterances and across turns are organized and meaningful (for example, the difference between the placement of a vocative at the beginning, mid-point, or end-point of an utterance). The influence of CA as a tool for understanding and fostering speaking in second language learning contexts has grown in recent years. Ducharme and Bernard (2001) studied spoken interactions among learners of French, by means of microanalyses of videotaped conversations and post-task interviews aimed at incorporating the perspectives of the participants. CA was also used by Mori (2002), who analyzed a speaking task performed by nonnative-speaking learners (NNS) of Japanese, where learners interacted with Japanese native speakers (NS) who had been invited to the class. The intention was to encourage freer, natural conversation, but the NS–NNS interaction in Mori's case revealed the characteristics of an interview, with questions from the students and responses from the NS guests, an undesired outcome. More natural discursive exchanges happened when the learners made spontaneous contributions or when they paid more marked attention to the moment-by-moment progression of the talk. Key to the interpretation of such phenomena is an understanding of the participants' orientation toward the institutionalized nature of the task they had been set, and CA, it is argued, facilitates such understanding. The CA-based view is that aspects of activity design and implementation influence the outcomes of speaking tasks in ways that CA can elucidate and that CA can point to directions for the improvement of the design and implementation of speaking tasks. On the other hand, there has been criticism of the lack of a 'learning' dimension in CA studies of second language speaking, in that CA is a very locally oriented analysis that is not good at producing actual evidence of change and development in speaking ability over longer spans of time.

CA analysts also examine openings and closings in conversations and how speakers manage the topics they talk about or want to talk about. Topics generally shade smoothly into one another, without unnatural jumps, and in conversations between equals, the right to launch a topic belongs to any speaker, but the other participants must accept the topics and contribute to them before they can truly be said to be conversational topics. In short, topics are typically *negotiated* in everyday talk among equals. Again, questions relating to second language speaking pedagogy include the possibility of assembling a lexicon of topic-management expressions, such as *Oh, by the way*, *Going back to* . . ., and *As I was saying* (Dörnyei and Thurrell, 1994). Another related issue is the exercising of topical control (typically by the teacher) and the potential therein for losing opportunities for the introduction of topics of which learners have genuine knowledge. The question of motivation if topics are imposed on learners or whether it is preferable to allow learners to introduce and manage their own topics is also one of interest. Other issues include whether raising awareness of topic-boundary phenomena (such as metastatements or discourse markers) can help second language learners to listen more selectively to discourses such as university lectures and the way learners actually intervene in topical negotiation, including even in relatively 'traditional' language classrooms.

The DA approach has also been influential in research on second language speaking. In this approach, the smallest unit of interaction is seen as the exchange, which involves at least two turns: an initiation (I) and a response (R), for example, *How are you?* (I) *Fine*. (R). The most common pattern of spoken exchanges in the traditional teacher-fronted classroom is that of initiation (I), response (R), and follow-up (F), often called IRF exchanges. That is to say, the teacher initiates, the student responds, and the teacher then follows up, for example, *What color was the cat?* (I) *Black*. (R) *Very good*. (F). The original study in this area was carried out on L1 classroom data by Sinclair and Coulthard (1975) and it is often argued that the IRF pattern does not reflect the complex demands of everyday conversations outside of the classroom, especially since teachers most typically exercise the follow-up role, while learners languish in passive, respondent roles. However, Kasper (2001) took to task the commonly held view that IRF routines are a restrictive interactional format. Kasper argued that the negative reputation of the IRF exchange may not be entirely justified and that it is the kind of interactional status assigned by the teacher to individual learners that matters in how speaking occurs in the classroom. When learners are treated as primary interactants in speaking activities, teachers extend them more participation rights in the conversation. Kasper suggested that teachers can help learners to become actively involved in spoken interaction, even within the framework of the classic IRF patterning of teacher-fronted classroom talk.

McCarthy (2002), also starting from a DA base, suggests that R and F moves play a central role in the manifestation of 'listenership,' that is to say, verbal engagement in the discourse when one is not in the role of main speaker, a situation NNS typically find themselves in, especially at earlier stages of proficiency. Listenership is distinct from 'listening' in the conventional four-skills paradigm of listening–speaking–reading–writing, where listening is seen as receptive and is tested through comprehension tests. Listenership is instead a component of the speaking skill, since it demands appropriate verbal response as the main index of comprehension and engagement. The difficulty lies in the fact that many R moves and the vast majority of classroom F moves are produced by the teacher, resulting in impoverished opportunities for learners to engage in typical listener follow-ups as they occur in non-institutional, everyday conversations. Learners most typically experience the teacher's R and F moves only as peripheral participants (Ohta, 2001). Ohta advocated peer-to-peer interaction as offering more enriched opportunities for learners to engage in appropriate listener behavior. The happiest compromise seems to be exposure to the teacher's use of R and F moves accompanied by explicit guidance and instruction on the use of respondent moves to encourage learners to develop over time toward production of such moves in peer-to-peer speaking activities. In a framework that combines DA and CA elements, Walsh (2002) stressed the importance of distinguishing different modes of teacher talk and illustrated how different modes may hold back or optimize opportunities for second language learners to contribute via the distinct types of exchanges associated with each mode. Seedhouse (1996) also argued that traditional classroom discourse has been unfairly criticized by those advocating more 'communicative' pedagogies. He argued that the goal of creating 'natural' conversation in the second language classroom is basically unattainable and that it would be better to adopt an approach where classroom discourse is seen as an institutional variety of discourse, alongside other institutional varieties and alongside non-institutional varieties, in which the character of the interaction corresponds appropriately to institutional goals.

Interactional Sociolinguistics (IS) also provides an analytical framework for a number of studies of second language speaking. IS stems particularly from the work of Gumpertz (see Gumpertz, 1982). It is a microethnographic approach to the study of communication in the context of bilingualism and cross-cultural contexts. IS draws on CA and ethnographic approaches to look at audio- or videotaped interactions from the perspective of both the researcher and the participants. Research in this area is particularly focused on gaining insights into cross-cultural miscommunication and misperceptions when two cultures are involved in a spoken interaction. By scrutinizing the recorded interaction, participants can reflect on what they said, what they meant, and what they achieved. Boxer (2004) noted that IS offers rich contextualized analysis of talk-in-interaction that has important potential implications for of the study of second language speaking in SLA contexts. Halmari (2004), for example, conducted a 12-year study of the codeswitching patterns of two young Finnish Americans living in the United States. Her study illustrates 1) that codeswitching patterns may be seen as a reflection of developing discourse competences and 2) how the two languages are deftly altered in naturally occurring discourse among bilingual family members as a means of conveying a vast array of subtle pragmatic messages.

Speech Acts in Second Language Speaking

The study of speech acts is an area that is related to CA, DA, and IS, but studies in this field differ fundamentally in the data they use. Most studies into speech act realization in second language speaking have derived from elicited rather than spontaneously recorded data. This is because it can be difficult to gain access to data with rarely occurring or rarely recorded speech acts, or speech acts that do not readily occur in two languages that the researcher wishes to compare. One of the most common strategies is to use Discourse Completion Tasks (DCTs), which involve specially designed questionnaires that elicit responses. For example, they can provide a situation and leave a blank for the speech act to be supplied or provide a first turn followed by a blank. Multiple turns have also been employed to make DCTs more interactive. DCTs can alter contextual features, such as age, gender, and speaker status, to access varied responses from informants. Much discussion has taken place as to the adequacy of DCTs as a research instrument. They are criticized for making *a priori* decisions about sociolinguistic variables that are deemed to be important in a given situation (Boxer, 2004). Beebe and Waring (2004) designed a DCT-based study on rudeness that comprised six situations where someone was rude and the subject was asked to respond. The situations were selected from 750 naturally occurring examples of spontaneous rudeness. It involved 40 NNS participants from seven countries all enrolled in an Intensive English Language Program at a North American university. They were asked both what they would say and what they would feel like saying, so that the informants could respond (1) in a way that reflects social constraints and (2) in a way that reflects no social constraints that would hold them back. They found that the low-proficiency speakers tended to rely on sarcasm and intensifiers by repeatedly using a limited number of adverbs. The high-proficiency speakers, on the other hand, used a much wider range of adverbials to convey tone and managed to sound assertive without being hostile. Based on these and other findings, Beebe and Waring speculated that there is a cline of difficulty in acquiring pragmatic tone in second language speaking – intense and sarcastic tones are easier to acquire than more subtle tones of assertiveness or aggression.

Areas of Growing Influence and Debate in the Area of Second Language Speaking

Corpus Linguistics

The advent of the tape recorder changed not only how spoken language was taught but also how it was studied. Similarly, the availability of computers meant that large amounts of naturally occurring recorded spoken language could be transcribed and then stored on computer for analysis. Such principled collections of texts (spoken and written) are referred to as corpora. As a result, our knowledge of spoken language has changed significantly. Large corpora of spoken language are now collected and described. In the area of English as a Foreign Language, spoken corpora that have been or are being exploited for the teaching of speaking include the spoken components of the British National Corpus (100 million words in total, of which 10 million is spoken conversation) and of the Bank of English, the British/Irish CANCODE spoken corpus, the Michigan corpus of academic spoken English (MICASE), the Longman Spoken American Corpus, and the American National Corpus. Those studying the teaching of speaking note the growing influence of spoken corpora on the pedagogy of speaking and point out that new understanding has prompted new debates about the 'what' and the 'how' of the teaching of second language speaking.

In the context of English as a globally used language, new issues for second language pedagogical modeling arise with the collection and description of different varieties from around the world. In the case of English, the International Corpus of English (ICE) project makes available spoken data for the Englishes of Hong Kong, New Zealand, Singapore, Great Britain, Nigeria, and the Caribbean, with others under development, and Ireland can count on both ICE and the Limerick Corpus of Irish English (LCIE), all of which are either aimed at or have direct implications for the improvement of second language speaking. Though English dominates the present discussion, it is apparent that similar problems exist in the establishment of pedagogical models for the speaking of multi-national languages such as French and Spanish. North American universities often insist on the spoken model of metropolitan France rather than that of nearby French Canada and publishers routinely sanction language teaching materials for use in Latin America in terms of their faithfulness to European (Castillian) Spanish norms. Corpora are also currently influencing the teaching of spoken French, with similar debates about the modeling of spoken language for pedagogy as those under way with regard to English (Lawson, 2001).

Research into language corpora has frequently shown that there is a discrepancy between the language we use and the language we teach (see, for example, Holmes, 1988). A recent example is the finding by corpus analysts and other linguists that fixed 'chunks' of various kinds have a central role in everyday, fluent speech. Wray, investigating

formulaic sequences (which include idioms, collocations, and institutionalized sentence frames), stressed that such sequences circumvent the analytical processes associated with the interpretation of open syntactic frames in terms of both reception and production and she criticized attempts to encourage the analysis of formulaic sequences in second language pedagogy as "pursuing native-like linguistic usage by promoting entirely unnative-like processing behaviour" (Wray, 2000: 463). Wray's work attempted to move away from a static, behaviorist account of formulaic language, emphasizing its nature as dynamic, responding to the demands of language in use. The study of the role of fixed sequences in second language contexts has been investigated by Schmitt and his associates (Schmitt, 2004), and emerging insights into the importance of the acquisition of chunks in second language speaking continue to flow from corpus-based studies of both first and second language speaking.

NS versus NNS Models for Second Language Speaking

Another ongoing debate centers on the comparability of native versus nonnative speaking. Medgyes (1992) argued that a nonnative cannot aspire to acquire a native speaker's language competence and that native- and nonnative-speaking teachers reveal considerable differences in their teaching behavior and that most of the discrepancies are language-related. However, he noted that native and nonnative teachers have an equal chance to become successful teachers, but the routes used by the two groups are not the same. A number of publications debate the issue of NS versus learner corpora and NNS corpora (Seidlhofer, 2001; Prodromou, 2003). Prodromou, whose work is based on a mixed NS–NNS spoken English corpus, raised issues concerning the undermining effect of NS spoken corpora for NNS faced with language varieties and cultures that they can never appropriate completely for themselves. Reacting to similar concerns, Seidlhofer proposed a spoken corpus of English as a Lingua Franca (ELF) to profile ELF as robust and independent of English as a native language and to establish "something like an index of communicative redundancy" with pedagogical applications (Seidlhofer, 2001: 147). The shift away from the NS as the sole model for second language speaking is further underscored by the introduction into the debate of terms aimed at leveling the playing field between NS and NNS as potential models. Building on earlier work, such terms include 'expert users' and 'successful users of English,' with a focus on the modeling of successful language users (whether NS or NNS) in non-pedagogical contexts. Meanwhile, the Louvain International Database of Spoken English Interlanguage, set up in 1995, provides spoken data for the analysis of learner language.

Second language speaking is a complex affair and many aspects of research and observation of first and second language behavior have contributed to our understanding of the process. The future promises more data-based studies of second language speaking and more delicate descriptions of second language speaking on its own terms, rather than simply as an impoverished reflection of first language speaking.

Second Language Studies: Curriculum Development

J D Brown, University of Hawai'i at Manoa, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

One problem that arises in discussing curriculum development with language educators from many different countries is that different terminology is used in various places around the world. Hence, this article will begin by defining some key terms. Language class and course will refer to the regular meetings of a relatively small group of language students usually over a defined period of time with a particular teacher. A language program will be defined as a collection of such classes or courses in a single institution (e.g., a language school, university, school district, or state). Language curriculum will refer to the selection and structure of the content and learning processes of a language course or program. Also, language curriculum development will be defined as any systematic effort to create or improve the selection and structure of the content and learning processes to fit the needs of the people in a particular language course or program.

Given those definitions, the purpose of this article is to provide an overview of what is known today about language curriculum development by discussing those factors in the literature that are seen as important in carrying out language curriculum development. To

Second Language Studies: Curriculum Development

J D Brown, University of Hawai'i at Manoa, Honolulu, HI, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

One problem that arises in discussing curriculum development with language educators from many different countries is that different terminology is used in various places around the world. Hence, this article will begin by defining some key terms. Language class and course will refer to the regular meetings of a relatively small group of language students usually over a defined period of time with a particular teacher. A language program will be defined as a collection of such classes or courses in a single institution (e.g., a language school, university, school district, or state). Language curriculum will refer to the selection and structure of the content and learning processes of a language course or program. Also, language curriculum development will be defined as any systematic effort to create or improve the selection and structure of the content and learning processes to fit the needs of the people in a particular language course or program.

Given those definitions, the purpose of this article is to provide an overview of what is known today about language curriculum development by discussing those factors in the literature that are seen as important in carrying out language curriculum development. To

that end, the following six main headings will be used: (a) underpinnings of curriculum, (b) contexts of curriculum, (c) organization of curriculum, (d) information gathering for curriculum, (e) key questions in curriculum, and (f) outcomes of curriculum.

Underpinnings of Curriculum

The underpinnings of curriculum development are the language teaching approaches in which students, teachers, and administrators believe as well as their overall philosophies of curriculum development.

Approaches

Most teachers begin teaching a course with certain preconceptions and assumptions about what and how their students need to learn. These will be referred to here as approaches (after Brown, 1995a). For years, language teachers have drawn on a variety of disciplines (including psychology, linguistics, education, and other fields) in formulating their approaches.

One early strain of thought that emerged over the years was called the grammar-translation approach. Based on humanistic traditions and prescriptive notions of grammar, teachers believed that languages were learned primarily in order to access the knowledge of the world (i.e., the great books). As a result, teachers felt that their students needed to learn prescriptive grammar deductively through reading, translation, and memorization of passages from important texts in whatever target language was involved. Note that this approach, like the others discussed below, continues to influence teachers today – at least in some places around the world.

The direct approach continued to be affected by the notions of prescriptive grammar. However, in reaction to the grammar-translation approach, the adherents of the direct approach felt that students needed to learn meanings directly (i.e., they needed to associate meanings directly with the appropriate objects, movements, and gestures) and therefore needed to learn inductively while using only the target language. In addition, oral skills (listening and speaking) typically took precedence over written skills (reading and writing).

Based on language teaching developments during World War II, the audiolingual approach drew on descriptive linguistics and behavioral psychology – especially the ideas of operant conditioning and behavioral modification. Students' learning needs revolved primarily around inductive learning of listening and speaking (before reading and writing) through habit formation based on stimulus–response exercises such as pattern, transformation, and substitution drills.

The cognitive code approach, which developed as a counterpoint to the audiolingual approach, was based on the belief that language learning is a set of dynamic cognitive processes, not just a set of habits that must be formed. Thus, students were believed to need active participation in their own cognitive processes by consciously learning the structures and using the language.

The communicative approach concentrated on developing the students' communicative competence including the use of different registers and styles needed in different situations. It was also felt that students needed to be able to formulate meanings that were important to them in their own lives. This approach advocated the use of both inductive and deductive learning based on the best available knowledge (drawn from the analysis of natural discourse) about grammar, semantics, pragmatics, etc., as this knowledge applied to the particular communicative needs of a particular group of learners for reading, writing, listening, or speaking. This approach is currently the most influential one around the world – at least from a theoretical perspective.

Naturally, the five major approaches listed above are not the final and definitive listing. Other prominent approaches defining what and how students need to learn may have been overlooked here, and new and exciting ways of defining students' language learning needs are likely to evolve in our dynamic field. Perhaps content-based instruction (Brinton *et al.*, 1989) will emerge as *the* important approach, or maybe some other as yet unpublished approach will emerge. The main point is that approaches describe a set of options in which all language curriculum developers must take an interest.

Philosophies

Brown (1995a) discusses four philosophies that can underlie curriculum development: the discrepancy, democratic, analytic, and diagnostic philosophies. The discrepancy philosophy takes the view that students' needs are the differences, or discrepancies, between what they can actually do and what the teachers think they should be able to do. For example, teachers may want their students to be at a high level of academic English ability so they can succeed in an American university, but observe that they are currently at a low level.

The democratic philosophy takes the view that students need to learn whatever the majority of the group thinks they should learn. Whether this group is defined as the students themselves, their teachers, program administrators, or the language school owners, the democratic philosophy leads to teaching the students whatever the majority of the group thinks appropriate.

The analytic philosophy takes the view that students will learn better whatever they need to learn next in the hierarchy of language development. Thus, this philosophy might lead to a curriculum based on what is known about language learning and the hierarchy of language development steps.

The diagnostic philosophy takes the view that students need to learn whatever would prove harmful by its lack. This philosophy might lead to curriculum that includes the important language skills necessary for students to survive on a day-to-day basis in the target language community.

Contexts of Curriculum

The contexts of curriculum have to do with the many possible levels at which it can occur, but also have to do with the purposes of the curriculum development process.

Levels

Curriculum development can take place at many levels, including at least international, national, state or province, county, school district, multiprogram, program, and classroom levels. The scale is obviously different for the various levels and the complexity of getting things accomplished can grow exponentially with increases in the numbers of people and the sizes of egos involved, depending also, of course, on the political realities of the situation (for more on this issue, see Brown, 1993).

Purposes

One of the factors in curriculum development that is often overlooked is the wide variety of purposes the process can serve. Naturally, curriculum development can help create sound pedagogy. However, it can also have residual effects that provide renewed purpose for the program, foster leadership, help maintain or gain control of resources, furnish necessary political structures, help give a voice to different constituencies, build consensus, resolve conflict, adapt to change, change practices, plan future policies and curriculum projects, ameliorate working conditions, foster professional growth, and provide knowledge for the whole field. Any or all of these purposes can provide motivation for curriculum development.

Organization of Curriculum

In organizing curriculum, different aspects may need sorting out. Most commonly, organizing course content and organizing people are the two areas that need most attention.

Organizing Course Content

Syllabuses are defined here as the different ways of selecting and organizing the overall order of course content whether that be viewed as course materials or the associated teaching. In other words, it is the process of deciding what should be included and what should come first, second, third, etc.

Structural syllabuses focus on grammatical forms. Many textbooks and classroom materials have been organized around grammatical structures. The rationale is that those structures that are important in the language should be selected and then sequenced from easy to difficult (or sometimes, from frequent to less frequent). The grammar-translation and direct approaches tend to be organized around structural syllabuses.

Situational syllabuses are based on the idea that language does not exist in a vacuum but rather is found in a particular context or situation. Textbooks based on a situational syllabus tend to be organized around a variety of different situations. One text designed for Asian refugees in the United States might have lesson titles such as An Evening at School, At the Employment Office, At the Bank, etc.

Topical syllabuses are similar to situational ones, but are organized around various topics or themes instead of around situations. Thus, materials designed for junior college ESL students in the United States might have lesson headings such as The Two Party System, Women's Liberation, Rising Crime, etc.

Functional syllabuses are typically organized around categories of semantic language uses, or things we do with language, called functions (after van Ek and Trim, 1991). For instance, an adult school English course in Utrecht, Holland might be designed to teach general-purpose social English and be organized around language functions such as Greeting, Seeking information, Inviting, etc.

Notional syllabuses are organized around conceptual categories called general notions (again, after van Ek and Trim, 1991). General notions include abstract concepts such as Shape, Position, Direction, Quantity, etc. This type of organization is related to the functional syllabuses in that notions sometimes serve as a general set of categories within which functions are also organized. Notional syllabuses are much less common than functional ones, but nonetheless have existed for some time.

Skills-based syllabuses are organized around language skills that the students will need in order to use the language. For instance, in a reading course, the skills might include Guessing Vocabulary from Context, Using Prefixes, Roots and Suffixes, Skimming, Scanning, etc.

Task-based syllabuses are organized around different types of tasks that students might need to accomplish with language in their real lives. Such tasks might include Giving and Following Directions, Filling out Forms, Writing a Check, etc.

Sometimes, syllabuses are mixed. For example, situational and topical syllabuses were mixed in my first college Spanish language textbook resulting in a mixture of situations (e.g., *en un restaurante español, en un hotel mexicano*) and topics (e.g., *fiestas, los deportes*). More often, syllabuses are layered. In the example above, the mixed situations and topics were together layered over a structural syllabus that flowed through all the chapters.

Organizing People

As pointed out in Brown (1993), Toffler (1991: 187–194) lists seven different strategies for organizing the people in any kind of institution. A pulsating organization is one that regularly expands and contracts in response to changes in the need for its products or services. Many educational institutions are pulsating in the sense that they contract in the summer and expand during the school year; their summer schools are often pulsating in the opposite direction.

A two-faced organization operates with two separate chains of authority that change depending on the circumstances. For instance, a language program might operate with an authoritarian structure during the curriculum planning process, but on a more egalitarian basis once teaching begins.

A checkerboard organization allows for two points of view to be represented throughout the organization such that the management is structured with interlocking roles in the hierarchy for the people representing the two alternative viewpoints. For example, binational language programs often adopt this sort of structure (e.g., the GELC (Guangzhou English Language Center) program described in Brown, 1995a).

A commissar organization promotes the flow of information through two main channels throughout the organization. For instance, the China program mentioned in the previous paragraph had some of this sort of organization as well, with one line of communication to the PRC Ministry of Education and another going to UCLA in California.

A buro-baronial organization is a bureaucracy that includes small feudal-like baronies with 'lords' who rule over people who function like serfs. This was of course the structure of feudal societies wherever they existed in the world, but ironically appears to also be the structure of most universities.

A skunkworks organization is one in which a team of people is assigned a loosely defined goal to reach or problem to solve, provided with the required resources, and left alone to work on their own outside any other existing organizational structures.

A self-start team is similar to the skunkworks organization, but is self-organized. A group of people comes together to deal with a common goal or problem. The group then finds its own resources and proceeds to work together, perhaps on a computer network, outside any other existing organizational structures.

All in all, Toffler's seven ways of organizing people in institutions seem to describe rather well the options that we need to consider in curriculum development.

Information Gathering for Curriculum

Information gathering for curriculum development involves different types of information, various foci of information, and a number of information-gathering tools.

Types of Information

Quantitative information versus qualitative information One continuum of information types might be labeled with quantitative information at one end and qualitative information at the other (for more on this, see Brown, 2004b). Quantitative information is typically countable and therefore usually gathered using instruments that produce numerical results in the forms of test or quiz scores, grades, student rankings, the numbers of students in each class, etc. Qualitative information is more likely to be based on observations that are not readily quantified such as student diaries, teacher journals, faculty meeting minutes, classroom observations, interviews, etc.

Objective needs versus subjective needs Another continuum of information types can be labeled with objective information at one end and subjective information at the other. Theoretically, objective information is not biased by the observer and is based on clear-cut, observable data gathered about the situation, the learners, their present proficiency, their language goals, etc. Subjective information is generally more difficult to defend because it may be biased by the observer or object of study. Such information may be about the students' or teachers' feelings, wants, desires, beliefs, and expectations (Brindley 1984: 31) and therefore may be particularly skewed by the points of view of the observers and the observed. This is not to say that such points of view are not important for curriculum developers to know about.

Curriculum development should probably be based on all types of quantitative and qualitative information as well as objective and subjective information.

Striking a balance is the trick, a trick that will depend in part on the focus of the information being sought.

Focuses of Information

Situation information versus language information Situation information will typically center on the political and other human aspects of curriculum, especially about the social, psychological, and physical contexts and constraints in which learning is taking place. Such information may be related to the personal, pedagogic, administrative, financial, logistic, cultural, or other factors that impact on a curriculum.

In contrast, language information is about the target linguistic behaviors, goals, and objectives of the program. Language information would logically include details about things like the students' reasons for learning the language, the present abilities of the students with regard to those reasons, the conditions under which the language will likely be used, etc.

Information about linguistic content versus learning processes Other focuses for information may involve the linguistic content that students must learn as opposed to the learning processes that they go through to learn that content. The linguistic content viewpoint focuses on curriculum information about the content that will be taught such as phonemes, morphemes, structures, utterances, functions, discourse markers, etc. The learning process viewpoint is more likely to focus on factors that will affect the students' learning such as motivation, self-esteem, attitudes, learning strategies, learning styles, etc. This distinction between linguistic content and learning processes is far from new. It corresponds roughly to Widdowson's (1981: 2) concepts of 'goal-oriented' versus 'process-oriented' views of language learning needs; Brindley's (1984: 31–32) 'language content' and 'learning content' duality; Nunan's (1985) 'content' and 'methodology' parameters; and White's (1988: 44–61) 'Type A What is to be learnt' and 'Type B How is it to be learnt' syllabuses. Regardless of the terminology used, responsible curriculum developers will need to gather and use information about both linguistic content and learning processes.

Information-Gathering Tools

Curriculum developers will also need to gather the information using the appropriate tools. As discussed in Brown (1995a: 45–59), these tools come in six basic forms. Existing information might involve examining a particular institution's records or the records of several institutions, reading the literature of the field related to the particular type of curriculum involved, making phone calls, writing letters, sending e-mail messages, etc. Tests of all kinds can be used to assess the abilities of the participants in a program, whether they be for criterion-referenced diagnostic, progress, or achievement purposes, or for norm-referenced aptitude, proficiency, or placement purposes. Observations tend to take the forms of case studies, diary studies, behavior observations, interactional analyses, inventories, etc. Interviews often involve individual face-to-face interviews, telephone interviews, or group interviews. Meetings are useful for getting advice from people on curriculum issues, for resolving conflicts between interest groups, or for getting feedback from participants. Questionnaires can be used to gather relatively large-scale biodata information, self-ratings, opinions, or judgments on various aspects of a curriculum. The trick with all these information-gathering tools is to select and use only those from the long list of possibilities that will provide a balance of information types and lead to addressing the various focuses necessary in curriculum development.

Key Questions in Curriculum

The key questions in curriculum are who, what, and how, all of which are important questions related to the mechanics of getting things done in curriculum development.

Who? – Stakeholders

Who should be involved in curriculum development? The best answer to that question is: any stakeholders (i.e., any people who have a reason to care whether it succeeds or fails) should be involved. Of course, the degree and manner of involvement will probably vary from group to group, and the roles that they will play may vary as well: some groups may serve as important sources of information, whereas others give advice, and still others would be most useful for reviewing the results of the curriculum development process and giving feedback. Some groups may serve two or more of these functions. The potential groups of stakeholders would naturally include the students, teachers, and administrators who are most intimately involved in the curriculum, but other groups may also be important, such as parents, future employers, future professors, higher authorities in the institution, politicians, and the public (for more on stakeholders, see Brown, 1993).

What? – Components

The components discussed here are taken from Brown (1995a) and are the main curriculum

components typically listed in the systems approach to curriculum development (for more on the systems approach, see Dick *et al.*, 2000). This list describes both a set of steps that can be taken to develop a curriculum and a set of components for the revision and maintenance of an already existing curriculum. The basic components are needs analyses, goals and objectives, testing, materials, teaching, and program evaluation.

Needs analysis Needs analysis in language curriculum is often seen as the process of identifying the language forms that students ultimately will need to use in the target language. However, since the needs of the teachers, administrators, employers, institutions, etc. also have some bearing on the language learning situation, many other types of quantitative and qualitative information of both objective and subjective types must be considered in order to understand both the situation and the language involved as well as information on the linguistic content and the learning processes. Needs analysis is defined here (after Brown, 1995a: 36) as "the systematic collection and analysis of all subjective and objective information necessary to define and validate defensible curriculum purposes that satisfy the language learning requirements of students within the context of the particular institutions that influence the learning and teaching situation." (For recent work on needs analysis, see Brown, 1995a; Iwai *et al.*, 1999; Witkin and Altschuld, 1995).

Goals and objectives One logical outcome of a needs analysis is the specification of goals and objectives. Goals are general statements about what needs to be done in order to satisfy the students' needs. In contrast, objectives are relatively precise statements of the content and/or skills that the students will have mastered by the end of each course. Objectives can take many forms and will probably differ in terms of their degree of specificity even within a particular program. Objectives are often drawn from or related to taxonomies of various types (for more on taxonomies and objectives, see Brindley, 1984; Brown, 1995a; van Ek and Trim, 1991).

Language testing Meeting the needs of the students and addressing the resulting goals and objectives may necessitate a fair amount of test development for a variety of different purposes. From a norm-referenced perspective (i.e., a standardized testing perspective), it may be necessary to decide who should be admitted to the program by using proficiency tests; for students already in the program, it may be necessary to place students in different levels of study using a placement test. From a criterion-referenced perspective (i.e., a classroom testing perspective), diagnostic testing may be needed at the beginning of a course to determine the students' relative strengths and weaknesses vis-à-vis the course objectives, and achievement testing will undoubtedly be necessary for purposes of grading or deciding who should pass or fail each course (for more on the distinction between norm-referenced and criterion-referenced testing, see Brown, 1995a, 2004a, or Brown and Hudson, 2002; for classroom testing ideas, see Brown, 1998).

Materials Having done needs analyses, and having developed goals and objectives, as well as the appropriate tests, curriculum developers are in the remarkable position of being able to deal logically with materials. Adopting, adapting, or creating materials is relatively easy in a curriculum that has well-developed needs analyses, objectives, and tests. In fact, deciding which strategy to use, that is, adopting, adapting, or creating materials, will itself be made easier. Can existing materials be adopted to fill the needs of the students? Or should existing materials be adapted so they meet the students' needs as expressed in the curriculum objectives? Or, if there are no existing materials that will work, should the materials be created from scratch? (For more on materials development, see Brown, 1995a; Byrd, 1995; McDonough and Shaw, 2003; Tomlinson, 1998, 2002.)

Teaching In any curriculum, teachers need support in the sense that they may need the following: orientation to the program when they arrive; observation and feedback; in-service training opportunities; incentives to engage in professional development; and so forth. Failure to provide these sorts of teacher support can lead to low morale, teacher burnout, and attrition. In contrast, a high level of teacher support will help them grow professionally, which, in turn, can lead to better morale and less teacher burnout. To some degree, teacher support may entail involving them intimately in the curriculum development and revision processes. All in all, teacher support should be designed to help teachers do what they do best—teach. (For more on teaching issues, see, e.g., Brown, 1995a; Pennington, 1995; Richards and Lockart, 1994).

Program evaluation Brown (1995a: 218) defined program evaluation as "the systematic collection and analysis of all relevant information necessary to promote the improvement of a curriculum and to assess its effectiveness within the context of the particular institutions involved." This definition is very

similar to the one provided above for needs analysis. Indeed, it is fair to say that program evaluation is a sort of ongoing needs analysis—one based on considerably more and better information. A needs analysis is usually conducted in the beginning stages of curriculum development, whereas program evaluation can take advantage of all the needs analysis information, but can also use all the information gathered in the processes of developing objectives; writing and using the tests; adopting, adapting, and creating materials; and supporting teachers. Such a continuing process of evaluation makes possible the assessment of the quality of all the components of a curriculum once it is in place, as well as the maintenance of that curriculum in an ongoing manner (for more on language program evaluation, see Alderson and Baretta, 1992; Brown, 1995a, 1995b, 2001; Brown and Rodgers, 2002; Lynch, 1995, 2003; Rea-Dickins and Germaine, 1992, 1998).

How? – Logistics

Even under the best of conditions, curriculum development will take a great deal of time and effort. Indeed, if curriculum development is viewed as an on-going process of development and maintenance, it will never be totally finished. Hence, curriculum developers should think in terms of setting up structures that will foster continued curriculum development. At some level or other, the logistics of curriculum development must involve at least the following seven steps:

1. Finding and marshalling resources;
2. Setting up structures to help teachers do their teaching;
3. Providing political structures and leadership that will help the teachers to work together and pool their abilities;
4. Dispensing the available resources equitably;
5. Buffering the teachers from external negative forces so that they can get on with curriculum development projects;
6. Representing the curriculum to the outside world;
7. Starting the whole process over again with Step 1.

In short, effective curriculum development must supply suitable logistical structures and safeguards so that those who are closest to the students will be able to investigate their needs, set goals and objectives, develop tests and materials, and teach, and then, continuously revise all of the elements through on-going program evaluation procedures. It is essential to provide logistical structures that will promote the purposes of the curriculum and, at the same time, provide enough freedom so that teachers can focus on their teaching.

Outcomes of Curriculum

Finally, in thinking about the outcomes of curriculum, we must consider the audiences involved, dissemination of the results, and the benefits to be derived.

Audiences

The issue of audiences involves deciding who should receive information about the results of any curriculum development efforts. They will typically be subgroups of the stakeholders, or groups of those people who need to be informed about the curriculum development, or need to be influenced, or impressed with all the hard work. Some groups may need a complete and detailed report of the results, whereas others may need only an 'executive summary' of one or two pages. The potential audiences would probably include at least the students, teachers, and administrators at the institution, but might also include higher authorities at the institution, politicians, the public, etc.

Dissemination

As mentioned just above, it may make sense to have reports of different lengths for different audiences. It can also make sense to deliver oral reports to some audiences, written reports to others, and combined oral/written reports to still others. For instance, a full hour-long oral presentation and a detailed handout might be appropriate at a full faculty meeting, whereas a short oral report might be better for the university president (accompanied by a written executive summary for later perusal), and then further written dissemination might be needed in the form of a full-length written curriculum document for the curriculum developers within the program. Other forms of dissemination might also be useful. A news release sent to local newspapers can be useful for informing the public of curriculum development efforts or a short article written for institutional or professional newsletters will let colleagues in other language programs know about the curriculum development project. Or, for even wider dissemination to the whole language-teaching field, presentations at professional conferences or articles in relevant journals and books might be useful.

Benefits

The results of any curriculum development project should be used in a variety of ways to benefit the course or program. Yes, it can be used to create sound pedagogy, but also to foster better leadership, gain control and maintain control of resources, create better political structures, afford different constituencies a stronger voice in the program, help build

UNDERPINNINGS OF CURRICULUM	
Approaches	***Philosophies***
Grammar-translation	Discrepancy
Direct approach	Democratic
Audiolingual	Analytic

Figure 1 The many facets of language curriculum development.

consensus on important issues, resolve conflicts, help in adapting to change, create better practices, promote rational planning for future policies and curriculum, ameliorate working conditions, foster professional growth for teachers and administrators, and provide more knowledge for the field as a whole. Notice that these benefits have brought us full circle to the purposes of curriculum development listed much earlier in this article, which were exactly the same. Clearly, then, the very purposes of curriculum development offer benefits well beyond the development of sound pedagogy for the students.

Conclusion

In short, curriculum development involves at least the six major categories of curriculum activities listed in this article, which included a total of 15 curriculum facets and almost 100 individual subparts (see Figure 1). It is important to recognize that all of these categories of activities, facets, and subparts may interact with one another; that is, choices made with regard to one subpart will affect the choices that can be made with respect to other subparts. All of this can seem rather daunting if not framed clearly in terms of the tremendous benefits that can accrue from doing curriculum development.

Introduction

Context

In light of increasing globalization and written electronic communication, worldwide interest in second language writing (L2W) has increased rapidly during the past 25 years. L2W instruction is available from kindergarten through graduate school and beyond.

However, while work on L2W and writing instruction is now being done throughout the world, across educational levels, and in a number of languages, the majority of work to this point has been done in North America (due to the existence of required composition courses) at the college level (where research is most viable) in English (due to its dominant position in the world). This bias will be reflected in what follows. Fortunately, scholarship on L2W and writing instruction is growing rapidly in Europe, Asia, Australia, and elsewhere; thus, it can be expected that in the next 25 years, L2W and writing scholarship will become truly international in scope.

Definitions

L2W will be defined here as writing done in a language other than one's mother tongue. The term 'second language' will encompass both second (writing in a context in which the target language is dominant) and foreign languages (writing in a context where the target language is not dominant); 'writing' will refer to composing written text (as opposed to orthography). In a more general sense, L2W will be seen as purposeful and contextualized communicative interaction that involves both the construction and the transmission of knowledge; its basic elements are the writer, the reader, text, and context, and the interaction of these elements in authentic settings.

History

L2W studies has grown primarily out of work done in applied linguistics and composition studies. A brief account of the recent history of composition studies and applied linguistics will be offered to provide context for the examination of the history of L2W.

Composition Studies

The roots of contemporary composition studies in North America, defined as the study and teaching of writing, can be traced back to the beginning of the 19th century. The model for first-year composition was a course that focused on reading and writing about the canonical literary works of the day. What students were taught about grammar, style, and organization, which were the staples of this course, was derived from these works.

Early in the 20th century, resistance to the belletristic focus and the imposition of the literary canon on writing courses began to mount. This resistance promoted student self-expression in writing, the social utility of writing courses, and the preparation of students to function in a democratic society.

With the advance of the 20th century, the division between literary scholarship and the teaching of writing in English departments grew wider. The increasing independence of the discipline of composition studies was reflected in its professionalization, examples of which are the founding of a professional organization and a scholarly journal. Other manifestations of the maturing of the field included advocacy for writing teachers and program administrators, the incorporation of knowledge from other disciplines, and the expansion of different avenues of inquiry (specifically, a move toward empirical research in composition).

The second half of the century brought even greater independence and change. The 1960s saw the return of classical rhetoric, the beginning of empirical study of composing processes, and an increased focus on the notion of a writer's authentic voice. The 1970s brought the notion of writing as a cognitive process and its application in both teaching and research, the recognition of student diversity in language and culture, the distinction between home and school language, and the encouragement of teachers outside of composition studies to give serious attention to teaching students how to write in their own disciplines.

In the 1980s, writing began to be seen as a sociocultural as well as a cognitive process and as an interdisciplinary field. Rhetoric became epistemic, involved in creating as well as transmitting knowledge, and the notion of discourse communities strongly took hold. The process of professionalization continued with the proliferation of graduate programs in composition studies, the establishment of a national center in the United States for the study of writing, the production of a comprehensive bibliography of composition scholarship, and an increase in outlets for publication overall. Tension between literature and composition faculty in U.S. departments of English also grew. Composition studies had become overtly political and had begun to inquire seriously into issues such as race, class, and gender.

The 1990s saw growing interest in postmodernism and cultural studies, social constructivist thought, and historical and archival studies of the field, all a function of an increasingly reflective attitude among composition professionals. Also foregrounded were longitudinal empirical research, a critique of composing process research and pedagogy, an increased focus on diversity with regard to language and cultural issues, and an explosion of interest in the use of computers and related technologies.

Applied Linguistics

It can be argued that applied linguistics has been around for hundreds of years. However, most commentators place the birth of contemporary applied linguistics, at least in North America, near the middle of the 20th century, particularly in 1941, with the founding of English language institutes and the establishment of applied linguistics journals. The motivation for all of this focus on language research was to a great extent the need for language training for military personnel in World War II. The theory that followed was a blend of American structuralist linguistics and behaviorist psychology; its manifestations, among other things were contrastive analysis, instruction based on the notion of operant conditioning, and discrete point language testing.

In the 1950s, applied linguistics' primary focus remained on L2 instruction, although there was some work on literacy and language arts. This decade also saw the appearance of graduate programs in and centers for applied linguistics. In addition to work on language teaching, the 1960s brought increased interest in language assessment, language policy, and the incipient research area of second language acquisition. The theoretical basis of applied linguistics began to move from structuralism to generative grammar, which would influence the field only indirectly via psycholinguistic inquiry that would later spawn the notion of interlanguage and studies in second language acquisition. This decade also saw the establishment of national and international professional applied linguistics organizations.

In the 1970s, while the foci of the 1960s continued, there was growth and interest in such areas as bi- and multilingualism, the rights of linguistic minorities, language policy and planning, and teacher training. In addition, new theoretical orientations that continue to the present day were put forward. These orientations included anthropological and sociological ideas that led ultimately to the influential notion of communicative competence. This work later manifested itself in the functional analysis of discourse, the development of courses in language for specific purposes, and the linguistic study of genre.

Applied linguistics in the 1980s began to go far beyond focusing on L2 learning and pulling work from only linguistics, psychology, and education. New foci included studying language use in academic and other professional settings, translation, lexicography, language and technology, and corpus linguistics; new disciplinary areas of influence were anthropology, sociology, political science, public administration, and English studies, particularly composition, rhetoric, and literary theory.

The 1990s and the first years of the new millennium brought even further expansion of work in applied linguistics, especially in terms of language learning and teaching (e.g., language awareness, attention and learning, task- and content-based learning, teacher/action research), in the critical appraisal of previous and current work (e.g., in language analysis, pedagogy, and rights), in ethical issues in language teaching and assessment, and in the viewing of applied linguistics as a discipline that mediates between research and practice.

Second Language Writing

Although developments in L2W have been greatly influenced by work in composition studies and applied linguistics, the unique contexts of L2W require distinct perspectives, models, and practices. In the recent history of L2W, a number of approaches or orientations (more or less specific to L2W) have vied for the attention of L2W professionals. These approaches or traditions will be addressed in order of their appearance on the L2W stage.

Controlled Composition

Controlled composition can be seen as an offshoot of the audiolingual approach to language teaching in that it shares two of its central tenets: the idea that language is speech (from structural linguistics) and that learning is habit formation (from behaviorist psychology). Thus, it is not difficult to understand why, within this tradition, writing is regarded essentially as reinforcement for oral habits and as a secondary concern.

In the controlled composition classroom, the primary focus is on formal accuracy. The teacher employs a controlled program of systematic habit formation in an attempt to avoid errors (presumed to be related to first language interference) and to reinforce appropriate second language behavior. Practice with previously learned discrete units of language is privileged over concerns about ideas, organization, and style; imitation and manipulation of carefully constructed and graded model passages are the central activities. Overall, in the controlled composition tradition, writing functions as a service activity, reinforcing

other language skills. The goal of writing instruction is habit formation. Students manipulate familiar language structures; the teacher is an editor privileging linguistic features over ideas. The text is seen as a collection of vocabulary or sentence patterns; there is negligible concern for audience or purpose.

Linguistic analysis dominated the research in this tradition and is still a major focus, though it has become more functional and less formal over the years. Early work in the linguistic analysis of second language writers' texts involved contrastive analysis (comparing the grammatical structures of two languages, for example, Spanish and English, in an attempt to ascertain structural differences, which were believed to pose the greatest problems for second language writers) and error analysis (locating, counting, and categorizing errors to discern patterns of error in written texts). Formal features examined include primarily lexical and syntactic phenomena; features such as number of words per t-unit and clause structures have been used to measure fluency, accuracy, and complexity in second language writers' texts.

Current Traditional Rhetoric

Increasing awareness of second language writers' need to produce extended written texts lead to the realization that there was more to writing than constructing grammatical sentences. The result of this realization was the ESL version of current traditional rhetoric (based on contemporary work in composition studies that focused on the written product, the analysis and classification of discourse, usage, and style), which emphasized the importance of organization above the sentence level. This approach owes much to the notion of contrastive rhetoric – the notion that writers' different cultural and linguistic backgrounds will be reflected in their rhetoric, with rhetoric typically (implicitly) seen as primarily a matter of textual structure. Thus, first language interference was believed to extend beyond the sentence to paragraphs and longer stretches of text.

The basic concern in this tradition was the logical construction and arrangement of discourse forms. Of primary interest, especially in the early years, was the paragraph, where the focus is on its elements (for example, topic sentences) as well as options for its development (for example, comparison and contrast). Another important concern was essay development, actually an extrapolation of paragraph principles to complete texts. This involved larger structural entities (for example, introductions) and organizational patterns or modes (for example, exposition).

Classroom procedures associated with this tradition have tended to focus students' attention primarily on form. At the most basic level, students are asked to choose among alternative sentences within the context of a provided paragraph or text. At a higher level, learners are instructed to read and analyze a model text and then apply the knowledge gleaned from this analysis to a parallel piece of original writing. At their most complex, exercises require students (already given a topic to write on) to list and group relevant facts, develop topic and supporting sentences on the basis of these facts, put together an outline, and compose a text of their own.

In short, this tradition sees writing as basically a matter of arranging sentences and paragraphs into particular patterns; learning to write requires developing skills in identifying, internalizing, and producing these patterns. The writer uses provided or self-generated data to fill out a pattern; thus, the reader is not confused by an unfamiliar pattern of expression. The text is made up of increasingly complex discourse structures (that is, sentences, paragraphs, sections, and so on), each embedded in the next largest form; and all of this takes place within an academic context, wherein the instructor's evaluation is assumed to reflect a community of educated native speakers.

By far, the largest single research focus in this tradition has been contrastive rhetoric. The focus of this work has been on characterizing how first language "cultural thought patterns" are reflected in second language writers' texts, how some cultures put the responsibility for successful written communication on the writer and others on the reader, and how differences between 'collectivist' and 'individualist' tendencies manifest themselves in L2W. The most commonly compared linguistic or cultural backgrounds have been Arabic, Chinese, English, Japanese, and Spanish. Contrastive rhetoric has been and is still a controversial issue, with some of its critics arguing that the notion can lead to stereotypes and others suggesting that the differences seen between groups are a matter of development rather than transfer. A number of other specific rhetorical features have been addressed in the literature. These include hedging, indirectness, reader orientation, introductions, metadiscourse, rhetorical preferences, and voice.

The Process Approach

Dissatisfaction with controlled composition and current traditional rhetoric, due to the belief that neither adequately engendered thought or its expression and to their perceived linearity and prescriptivism, paved the way for the process approach, another import from mainstream composition studies. This tradition sees the composing process as a recursive, exploratory, and generative process wherein ideas are discovered and meaning made. It is believed that guidance

through and intervention in the process was preferable to the imposition of organizational patterns or syntactic or lexical constraints and that, where there is a need or desire to communicate, content will determine form to convey meaning successfully.

In the classroom, the process tradition calls for providing and maintaining a positive, encouraging, and collaborative workshop environment and for providing ample time and minimal interference to allow students to work through their composing processes. The objective is to help students develop viable strategies for getting started, drafting, revising, and editing. From a process perspective, then, writing is a complex, recursive, and creative process that is very similar in its general outlines for first and second language writers; learning to write requires the development of an efficient and effective composing process. The writer is engaged in the discovery and expression of meaning; the reader is engaged in interpreting that intended meaning. The product (that is, the written text) is a secondary concern, whose form is a function of its content and purpose. In the process tradition, it is up to the writer to identify a task and an audience and to make the response to the former meet the needs of the latter.

The advent of the process approach prompted research on composing that focuses on the person (that is, the writer) and the process (that is, strategies) involved in writing. Many variables affecting second language writers have been identified and addressed in the literature. The second language writer has been looked at primarily in terms of the extent of transfer of first language proficiency or writing ability to L2W and the relationship between general second language proficiency and L2W ability. Also of interest are the possible connection between L2W ability and first language writing experience and expertise, writing apprehension, gender, learning style, language and instructional background, the second language writer's perceptions with regard to writing and writing instruction, and the amount of reading (in both first and second languages) a second language writer engages in. Research in this area has gone from seeing writer variables as simple and relatively discrete to very complex and greatly intertwined.

There is also a substantive body of scholarship on second language writers' composing processes. Predominant in this area are general composing process studies, that is, research that looks at L2W processes holistically. There are also studies that focus on particular subprocesses and elements of the composing process. The most common of these are studies of planning, drafting, revising, and editing. However, a number of other elements have also been examined. These include translating, backtracking, formulating, monitoring, the use of the first language when writing in the second, language switching, and the use of dictionaries and background texts when composing.

English for Academic Purposes

Perceiving theoretical and practical problems and omissions with regard to the process approach, critics suggested that the emphasis in ESL composition research and instruction be shifted from the writer to the reader, in particular academic and professional discourse communities. Most of the aforementioned criticism of the process approach came from proponents of an English for academic purposes orientation wanting to consider more seriously issues such as developing schemata for academic discourse, deriving insights from research on contrastive rhetoric, understanding what constitutes realistic preparation for academic work, learning about the nature of high-stakes academic writing tasks, giving students a better idea of how university writing is evaluated, and, generally, understanding the sociocultural context of academic writing.

Instruction in writing English for academic purposes focuses primarily on academic discourse genres and the range and nature of academic writing tasks. This instruction is meant to help students work successfully within the academic context. The instructional methodology suggested aims at recreating, as well as possible, the conditions under which actual university writing takes place and involves closely examining and analyzing academic discourse genres and writing task specifications; selecting and intensively studying materials appropriate for a given task; evaluating, screening, synthesizing, and organizing relevant information from these sources; and presenting these data in a form acceptable to the academy.

To sum up, in the English for academic purposes tradition, the emphasis is on the production of texts that will be acceptable at English-medium institutions of higher education; learning to write is part of becoming socialized into the academic community. The writer is pragmatic and interested primarily in meeting the standards necessary for academic success; the reader is a player in the academic community who has clear and specific expectations for academic discourse. The text is viewed as a more or less conventional response to a particular writing task that fits a recognizable genre; the context is the academic discourse community. Although the English for academic purposes tradition has grown and prospered, some have questioned its emphasis on writing in various disciplines (particularly in scientific and technical fields), pointing out the difficulty in learning and teaching the discourses of fields unfamiliar to L2W instructors.

Research in writing English for academic purposes has looked primarily at the issues of audience and, more recently, genre. The audience research has focused primarily on one particular readership: the academic discourse community, in particular, college and university professors and, to a lesser extent, editors of scholarly journals. This research has been performed primarily through surveys and addresses academics' beliefs, practices, expectations, reactions with regard to errors, literacy skills, and writing problems. The question of whether and how students should be initiated into the academic discourse community has also been debated.

In recent years, the study of genre in L2W has become very popular. In addition to general treatments of genre, many studies of particular written genres have appeared. Some address general types or modes of writing, such as narrative, descriptive, and argumentative writing as well as personal, academic, business, technical, and legal texts. A number of more specific text types addressed include summaries, essay examinations, laboratory reports, research papers, theses, dissertations, research articles, experimental research reports, and letters of reference.

Recent Trends

Recent years have seen the development of a number of new approaches, or perhaps it would be better to say extensions of prior orientations and traditions. These include a belletristic orientation focused on responding to literary texts and on reading and writing connections, an orientation based on work in critical theory and cultural studies, focusing explicitly on political and ideological matters, a genre orientation based on text analysis and work in corpus linguistics, and an orientation focused on general inquiry and rhetorical principles.

Current Status

For a long time (until the 1990s or so), L2W was primarily pedagogical in nature, borrowing, often uncritically, from composition studies and applied linguistics, working in their shadows, so to speak. However, in recent years, L2W has become a much more independent discipline in terms of mapping out its philosophical bases, theories, modes of inquiry, politics, and programmatic issues, as well as pedagogy.

Philosophy

Applied linguistics tends toward a positivist inquiry paradigm, with its realist ontology, objectivist epistemology, and empirical and manipulative methodology. It values certain truth and adopts a modernist orientation. Composition studies tend toward a relativistic paradigm, with its constructivist ontology, subjectivist epistemology, and hermeneutic methodology. It values consensus and adopts a postmodern orientation. The philosophical basis for inquiry in L2W studies reflects its lineage in the sense that it is a blend of the ideologies and inquiry paradigms of applied linguistics and composition studies. L2W studies favor a humble and pragmatic rationalism, with a modified realist ontology, an interactionist epistemology, and a multimodal methodology. It values contingent knowledge and adopts an orientation that incorporates elements of both modernism (e.g., progress, optimism, rationality) and postmodernism (e.g., relative and contingent knowledge, difference).

Theory

Applied linguistics theory grows primarily from linguistics; composition studies grow from rhetoric. Incipient L2W models and theories, in addition to drawing from these areas, look to psychological, sociological, educational, and other disciplines, and while there currently exists no well-developed theory of L2W, there seems to be a consensus that a such a theory would see L2W and first language writing as saliently different; address both the individual (cognitive) and social aspects of L2W; include consideration of second language writers' personal characteristics, composing processes, and written texts; be reasonably comprehensive and internally consistent; be informed by relevant work in relevant neighboring disciplines, and be sensitive to cultural, linguistic, and experiential differences of individuals and societies.

Politics

Current explicit commentary on political matters has its roots in work done in the early to mid-1990s. There were claims that L1 writing tended toward the ideological and L2 writing tended toward the pragmatic, and L2W professionals were warned against the uncritical acceptance of L1 writing ideology. In response to this, it was suggested that all forms of ESL instruction were political, that neutrality was a myth, and that a pragmatic position supports the status quo. It was also argued that L2 writing pedagogy is just as ideologically charged as L1 writing pedagogy, though not as openly articulated or discussed. In response came a denial of a necessary connection between pragmatism and an accommodationist ideology and a challenge to ideologist discourse. There was a call for adoption of critical theory and pedagogy, a critical pragmatism, and a subsequent critique of critical approaches to L2W.

A smaller cluster of work at the end of the 20th century and the beginning of the 21st century looked at ideology from a cultural perspective. It was claimed that L1 composition's principles and practices reflect an individualist ideology and that applying them with students whose culture may not share this ideology is problematic. In response, it was argued that, despite cross-cultural differences, such notions as voice, peer review, critical thinking, and textual ownership were not inherently individualistic. Other areas addressed included language bigotry in mainstream composition classes against speakers of nonprestige varieties of English; the role of power in the evaluation of L2 students' writing; L2W theory in terms of research methodology, discourse style, and gender sensitivity; the politics of textual production and consumption; how pedagogical approaches can help second language writers position themselves in vernacular and academic communities; strategies for advocating for ESL student support services; and the perceived efficacy of L2W instruction.

Research

Research in applied linguistics is typically empirical; research in composition studies is primarily hermeneutic. L2W studies employ both hermeneutic (narrative, historical, philosophical) and empirical (qualitative and quantitative) research methods to investigate both basic (the nature of the phenomenon of L2W) and applied (L2W instruction) problems.

In recent years, L2W research, has become better informed, theoretically and methodologically, has developed greater depth and breadth, has begun to use more mixed designs, and has gone from simple to more complex perspectives, toward a broad-based social understanding and toward greater inclusivity.

Specifically, its basic research foci have included writer characteristics (L2 writing ability, L2 proficiency, L2 writer background, and L1 influence on L2 writing), composing processes (planning, thinking, translation, rereading, revising, and editing), and written text (genre, organization, L2 text quality, text length, syntax, lexis, and errors). Its applied research foci have included content-based instruction, voice/identity, reading and writing, computers and technology, grammar and vocabulary, peer interaction, plagiarism, teacher response, literature, and film.

Programmatic Issues

Programmatic issues in L2W and writing instruction have been addressed mainly in three areas: assessment, instructional contexts, and instructional topics.

Assessment

Basic issues in assessment have included discussions of direct vs. indirect/objective writing tests; holistic, analytic, and primary trait rating; rater training; raters with or without experience with L2 writers; validity; reliability; and variables such as linguistic and rhetorical elements, subject matter knowledge, cultural expectations, nationality, reading comprehension, and amount of L1/L2 reading.

Instructional Contexts

Instructional contexts are discussed in terms of level (elementary, secondary, undergraduate, and graduate), aim (specific purposes vs. general categories), foci (composing processes, genre, grammar, and content), and type (basic/remedial, bilingual, immersion, submersion, sheltered L2, mainstream composition, cross-cultural, adjunct, writing across the curriculum, intensive L2 programs, and writing centers).

Instructional Topics

The main instructional topics that have been addressed include audience; cohesion; collaboration; computers and technology; conferences; content-based instruction; conventions; dictionary use; drafting; editing; error correction; freewriting; grading; grammar instruction; journals; literature; model/sample texts, peer review/response/evaluation/tutoring; plagiarism; planning/invention; portfolios; reading assignments; reading and writing; reformulation; research papers; sentence combining; sequenced writing assignments; teacher response; writing from sources; revising strategies; text analysis; topics/tasks/themes; translation; tutoring/writing centers; video/film; vocabulary; and workshops.

Future Directions

L2W seems to be moving toward a substantial treatment of three related issues: (inter)disciplinarity, professionalization, and inclusivity.

(Inter)disciplinarity

The field of L2W studies has come to view its parent disciplines neither as places to go for authoritative answers to its questions nor as role models to be emulated or imitated, but as areas with their own interests and agendas, strengths and weaknesses, and issues and problems that generate information and insights for L2 writing professionals to consider. While continuing to be sensitive to developments in other disciplines, the field of L2 writing has matured to the point of being able to resist the temptation to

try to import easy answers from other disciplines into the complex contexts of L2 writing. In addition, L2W studies have begun to draw on ideas from a number of other disciplines, e.g., psychology, sociology, and education.

Professionalization

The field of L2W studies has achieved a certain amount of independence and a distinct identity. It has a journal devoted exclusively to work in the area, professional conferences and symposia, book series, monographs, collections, and increased recognition in neighboring disciplines. However, it faces a number of challenges. One is continuity. It is the case that many specialists in the area do not work in Ph.D.-offering units, which prompts questions about where the next generation of L2W professionals will come from. Cutbacks in funding at research universities also make L2W studies vulnerable on this account.

To meet this challenge, it will be necessary for research universities with large numbers of second language writers in their graduate schools to recognize the need to hire full-time, tenure-track L2W specialists to run writing support programs and prepare teachers to staff these programs. It will also be necessary for Ph.D. programs in applied linguistics/second language studies and composition studies to see L2W as a viable research area and to accommodate students wishing to perform doctoral research in this area. That is, there will be a need for interdisciplinary cooperation and collaboration.

Inclusivity

As previously mentioned, currently, the majority of work done in L2W is carried out in North America with precollegiate and undergraduate college writers. For L2W studies to thrive, it will be necessary to encourage the expansion of L2W research, to look more and more closely at, for example, L2W in English outside of North America, in other second/foreign languages, in elementary and secondary schools, in bilingual education programs, with Deaf and hard-of-hearing students, in adult education programs, at the graduate level, and in the workplace.

Broadening the scope of L2W scholarship will require the efforts of scholars, publishers, and editors. Scholars will need to adopt a more global view, to promote a basic understanding of writing in general and L2W, to increase collaboration between specialists in North America and elsewhere, and to be willing to hold and attend conferences outside of North America.

Publishers and editors will need to create more outlets for publication outside of North America, to increase the accessibility of L2 writing scholarship, to distribute L2 writing research on-line, to be willing to publish research in languages other than English, and to start or continue to provide free or reduced-price copies (hard or electronic) of publications where prices are prohibitive.

Conclusion

The field of L2W studies is clearly becoming a mature discipline – it has begun to reflect on its history, reexamine its basic assumptions about L2W and writing instruction, synthesize research, and build models and theories. It is in transition from a tradition that sees L2W practitioners as consumers of imported instructional approaches and their accompanying research programs and ideologies to experienced and seasoned professionals with an understanding of the nature of L2W and a familiarity with relevant research from within and outside the field, who can reflect critically on knowledge of theory and on the results of inquiry from any relevant discipline so that they can develop their own models and theories, form their own research agendas, and, in their role as teachers, decide for themselves what makes sense for their students, for their objectives and teaching styles, and for their political, instructional, and classroom contexts.

Selectional Restrictions

K Allan, Monash University, Victoria, Australia

Language combines the meaning encapsulated in listemes (items listed in a lexicon) into the complex meanings of phrases, sentences, and longer texts. Such combination is conditioned by the rules of syntax and at least four kinds of selectional restrictions. Category features (Noun, Verb . . .) determine different morphological and collocational possibilities, for example, of *fly*$_{\text{Verb}}$ and *fly*$_{\text{Noun}}$ in *his hand flew to his fly*. Strict subcategorization identifies other syntactic categories that collocate with the listeme. Syntactically transitive verbs, for instance, are defined by some notational variant of the strict subcategorization feature [+ ___NP] 'takes a first object'; *open* (as in *Fred opened the box*) has this feature, whereas the intransitive verb in *the door opened easily* has the feature [– ___NP]. Supposedly, syntactic inherent features, such as [+ human, + female . . .] for *woman* or [+ active . . .] for *go*, have a semantic basis. The selectional features of one listeme refer to the inherent features of collocated listemes, for example, for a verb [+ [+ animate]___[+ abstract]] 'has an animate subject NP and an abstract first object NP.' So, there are no grounds for the syntactic selectional features originally postulated to constrain a supposedly purely syntactic process of lexical insertion into syntactic phrase markers; and the procedure is semantically conditioned. It would otherwise be impossible to generate meaningful sentences like (1) and (2).

(1) "Grace me no grace, nor uncle me no uncle." (Shakespeare, *Richard II* II.iii.87)

(2) "But me no buts." ([='don't prevaricate'] Scott, *The Antiquary*, Chap. XI)

Language combines the meaning encapsulated in listemes (items listed in a lexicon) into the complex meanings of phrases, sentences, and longer texts. Such combination is conditioned by the rules of syntax and at least four kinds of selectional restrictions. Category features (Noun, Verb . . .) determine different morphological and collocational possibilities, for example, of *fly*$_{\text{Verb}}$ and *fly*$_{\text{Noun}}$ in *his hand flew to his fly*. Strict subcategorization identifies other syntactic categories that collocate with the listeme. Syntactically transitive verbs, for instance, are defined by some notational variant of the strict subcategorization feature [+ ___NP] 'takes a first object'; *open* (as in *Fred opened the box*) has this feature, whereas the intransitive verb in *the door opened easily* has the feature [– ___NP]. Supposedly, syntactic inherent features, such as [+ human, + female . . .] for *woman* or [+ active . . .] for *go*, have a semantic basis. The selectional features of one listeme refer to the inherent features of collocated listemes, for example, for a verb [+ [+ animate]___[+ abstract]] 'has an animate subject NP and an abstract first object NP.' So, there are no grounds for the syntactic selectional features originally postulated to constrain a supposedly purely syntactic process of lexical insertion into syntactic phrase markers; and the procedure is semantically conditioned. It would otherwise be impossible to generate meaningful sentences like (1) and (2).

(1) "Grace me no grace, nor uncle me no uncle." (Shakespeare, *Richard II* II.iii.87)

(2) "But me no buts." ([='don't prevaricate'] Scott, *The Antiquary*, Chap. XI)

What governs the cooccurrence of listemes is that the collocation has some possible denotation (be it substance, object, state, event, process, quality, metalinguistic statement, or whatever). Consider three examples marked anomalous in McCawley (1968a: 265).

(3) *That electron is green.

(4) *I ate three phonemes for breakfast.

(5) *My hair is bleeding.

Example (3) is judged anomalous because electrons are theoretical constructs that cannot absorb or reflect light and that therefore cannot be predicated as green. But suppose an explanatory model of an atom were constructed in which an electron is represented by a green flash; there would be no anomaly in stating *that electron is green* with respect to such a model. Consider (4): Phonemes are abstract entities, and we cannot eat abstract entities. Now imagine a situation in which a breakfast cereal is made in the shape of letters (*à la* alphabet soup); this cereal is fed to participants at a Linguistic Society conference and some wag eats a <p>, a <t>, and a <k> and utters *I ate three phonemes for breakfast*. Such a statement is no more anomalous than Austin (1975: 144) saying *France is hexagonal* – which no one has judged anomalous. Take (5): Hair has no blood vessels, so it cannot bleed; but that would not stop a child painting bleeding hair or a computer game creating bleeding hair somewhere in cyberspace – both cases establishing conditions under which the utterance of (5) would not be anomalous.

Empirical evaluations of sequences of listemes for coherence and sense depend on what they denote; evaluations must be matched in the grammar by well-formedness conditions, in part expressed by selection restrictions. To describe the full set of well-formedness conditions for the occurrence of every listeme in a language entails trying every conceivable combination of listemes in every conceivable context, and such a task is at best impracticable and at worst impossible. One alternative is to systematically describe semantic frames for every listeme along the lines of Pustejovsky's (1995) 'lexical semantic structures.'

Seliverstova, Olga N. (1934–2001)

E V Il'chuk, The Moscow Pedagogical State University, Moscow, Russia

© 2006 Elsevier Ltd. All rights reserved.

Olga Nikolayevna Seliverstova was born October 17, 1934, in Moscow in a family of prerevolutionary Russian intelligentsia. In 1957 she graduated from Moscow University (Department of Germanic Languages and Literature) and subsequently began there her postgraduate study, obtaining in 1965 the Ph.D. degree (candidate's degree) with a thesis on the semantics of some Russian and English pronouns. In 1966 she was offered the post of a researcher at the Institute of Linguistics, Russian Academy of Sciences, where she worked in the Department of Germanic

Languages until she died in 2001. In 1983 she obtained the Doctor of Science degree with her thesis on 'Existentiality and Possessivity in Language and Speech,' later gaining the title of Professor and the post of a leading researcher at the same institution.

In her Ph.D. thesis and first publications she elaborated on her innovative approach to meaning and the methods of its research and laid the foundation for her original theory of pronominal semantics. She considered the meaning of the linguistic sign to be a mental concept which in speech is realized as the information the sign carries about its *denotatum* (referent). This approach to meaning allows one to differentiate between meaning and denotatum, meaning and context, meaning and extra-linguistic knowledge, which is of primary importance for semantic research. According to her view, semantic investigation should be based on strict experimental methods, and its conclusions should be substantiated by their conformity to empirical language material. Her scope of interests and her activity as a linguist were varied and widespread. She is the author of four books and more than 50 articles on semantic theory and research which deal with the most topical problems of semantics. For many years O. N. Seliverstova was the leading consultant on a Russian-French project on the semantics of Russian syntactic words. She conducted seminars in experimental semantics at the Institute of Linguistics, The Russian Academy of Sciences, and gave lectures in Russia, France, and Italy.

Her life as a scholar, seemingly uneventful, was a life of dedication to science, her family, colleagues, friends, and students. Many of her students were attracted by her charming and warm personality, rare talent, enthusiasm, and never-exhausting ideas which she was always ready to share with them. O. N. Seliverstova was a rare type of scholar, exceptionally gifted, who possessed a striking individuality, a powerful analytical mind, and unerring linguistic intuition combined with subtlety and thoroughness of semantic analysis. She always took her own independent stand in science based on her remarkable linguistic vision and personal integrity. Her mature ideas and principles of semantic research were supported by her rich creative powers, strength of mind, and personality. Her works made her a leader in the field, leaving far behind the average level of present-day linguistic studies, paving the way for future semantic research and blazing new trails in linguistics.

Her major achievements pertain both to semantic theory and to research. Among her notable contributions are fundamental studies dealing with (a) the theory of linguistic meaning and types of its semantic structure, (b) progressive elaboration of experimental methods in semantic research, (c) componential analysis (its theory and application), (d) the semantics of pronouns, (e) the semantics of syntax (mainly Russian and English existential, locative, and possessive constructions), (f) the communicative sentence perspective, (g) the problem of factivity, (h) the invariant meaning of the Russian perfective aspect, (i) the innovative and original semantic descriptions of numerous wordgroups in Russian and English: among others, pronouns, polysemous words, predicate types, verbs of thinking and perception, spatial-distance prepositions and adverbs.

Semantic Change, the Internet: and Text Messaging

A Deumert, Monash University, Victoria, Australia

© 2006 Elsevier Ltd. All rights reserved.

Electronic Communication: Efficiency and Expressivity

Since the 1980s, computer technology and mobile technology have given rise to various forms of text-based, electronic communication: e-mails, newsgroups, chatrooms, and, more recently, blogs (web logs that function as on-line diaries) and text messaging (Short Message Service, SMS). The language used in electronic communication has been described as a hybrid, showing both speech-like and writing-like features, as well as features that are unique to the digital medium and are, to some extent, the result of its technological restrictions. For instance, slow modems, limited bandwidth, costs, small screens, and typing speed are often cited as reasons for the preponderance of abbreviations in text-based electronic communication (cf. Baron, 2000; Shortis, 2000; Crystal, 2001).

The communicative need to use language efficiently within the constraints of the medium is complemented by the users' desire for conceptual and communicative expressivity (on efficiency and expressivity in semantic change cf. Geeraerts, 1997: 102–108). Crystal (2001: 67) has highlighted the "strong, creative spirit" that characterizes the language of Internet users: "The rate at which they have been coining terms and introducing playful variations into established ones has no parallel in contemporary language use." Linguistic creativity and playfulness can be described as conversational maxims of electronic communication and are most noticeable in recreational contexts (such as chatting and texting; Danet, 2001; Crystal, 2001: 168–170). Other conversational maxims (politeness, relevance, truth) can at times be suspended (or at least take second place; cf. Wallace, 1999: Chap. 3, on deception, masquerades, and lies on the Internet). Innovative in-group language use and a predilection for speech play was already a defining characteristic of those pioneer Internet users who engaged with the culturally still uncharted medium in the early 1980s. Raymond (2003) comments, e.g., on the popularity of form-vs.-content jokes among hackers (a person who enjoys exploring the workings and capabilities of programmable systems) and cites the tradition of 'hacker punning jargon' as an example. ('Hacker punning jargon' is the *ad hoc* use of intentionally transparent puns: FreeBSD → FreeLSD or IBM 360 → IBM Three-Sickly.)

Some Aspects of Semantic and Lexical Change in Netspeak and Texting

Users of electronic communication, despite their geographical dispersion, form a relatively cohesive, subcultural group and have been described as a 'virtual speech community' (Paolillo, 1999). Much linguistic work has concentrated on documenting the in-group national and international vocabularies that are used in electronic communication. The six standard categories of semantic change (cf. Traugott, 2000) can be identified in the specialist Internet lexicon (or jargon) that has its roots in hacker usage:

- Broadening/Generalization/Extension: *grep*, a UNIX command meaning 'Get REpeated Pattern,' is now used widely as a verb with the meaning 'to search.'
- Narrowing/Restriction: *banner* (top-centered graphic on a webpage), *to compress* (to reduce data size through the application of a mathematical algorithm).
- Amelioration: *nerd, geek* (which have acquired highly positive in-group connotations), *a hack* (a good and clever piece of work).
- Pejoration: *tourist* (an uninvited and usually non-participating guest on a discussion group), *random* (has a pejorative meaning of 'unproductive' 'undirected,' e.g., 'he is a random loser').
- Metaphor: *information superhighway, web-surfing, nipple mouse, gopher* (a software program designed 'to gopher' through information).
- Metonymy: *a suit* (someone involved in information technology who habitually wears suits and works in management, distinct from a real programmer or 'techie'; pejorative), *vanilla* ('ordinary' < vanilla ice cream, the default flavor in many countries, e.g., United States, United Kingdom).

Acronyms and abbreviations are a salient feature of what Crystal (2001) has called Netspeak, e.g., IRL 'in real life,' AFAIK 'as far as I know,' and BFN 'bye for now.' Media citations (from movies and computer games) have long been common in the in-group language of hackers and are moving into mainstream Netspeak: 'all your base are belong to us' is an expression used to declare victory or superiority (from a 1991 computer game; the citation spread through the Internet in 2001); 'and there was much rejoicing' can be used to acknowledge an accomplishment (from the movie *Monty Python and the Holy Grail*). Overlexicalization and the clustering of synonyms is another characteristic feature (e.g., *nick, handle, screen name,* and *pseudo* are all used to refer to the pseudonyms used by participants in chatrooms or newsgroups), as is the on-going creation of portmanteau neologisms

(*netiquette, newbie, progasm, screenagers*, etc.). There are also conventions for the encoding of prosody and paralinguistic meaning: emoticons (smiley icons such as :-)), the use of capitals (to indicate shouting), and repetition of letters (for emphasis) are used to disambiguate written messages.

With regard to derivational morphology: the *e* prefix and the *bot* suffix (from 'robot') have established themselves as productive morphemes (*e-loan, e-government, e-cards, e-books*, *annoybot, mailbot*, etc.). In inflecting languages, such as German, a new and productive lexical class has emerged in the context of chat communication: nonfinite verb-last stems. These are used by participants to describe actions that are performed in the context of the conversation. The action descriptions are inserted in asterisks: **away sei** (*away be*; the full German infinitive of 'to be' is *sein*), **schnell zu dir renn** (*quickly run to you*; the full German infinitive of 'to run' is *rennen*; cf. Schlobinski, 2001). Verbal stems (*schluck* 'swallow,' *gähn* 'yawn') have long been used in comics and also colloquially in German youth language. In English, on the other hand, action descriptions such as *nod* and *sigh* are structurally ambiguous and not necessarily identifiable as stems; moreover, inflected forms such as *shakes hand* are not unusual in English chat communication (Werry, 1996).

The lexical structure and character of nicknames ('nicks') is another aspect of the linguistics of Netspeak. In terms of semantic preferences, Bechar-Israeli (1996) identified six main semantic fields from which nicks are drawn: self-descriptors (<shydude>, <Dutchguy>, <irish>); technology (<Pentium>); real-world objects (<froggy>, <tulip>, <cheese>); play on words and sounds (<kukyMNSTR>, <whathell>); famous characters (<Elvis>, <Barbie>); and sex and provocation (<fuckjesus>, <sexpot>).

The language of text messaging/texting, which has become a popular form of interpersonal communication from the mid-1990s, is partially based on Netspeak, but shows a more radical use of abbreviations (e.g., 'it's prty low 4 sum 1 2 dump their b/f or g/f by sms' 'it is pretty low for someone to dump their boyfriend or girlfriend by sms'; special conventionalized abbreviations are also used in SMS, e.g., SWDYT 'so what do you think?'). The trend toward letter reduction (mostly achieved through a technique called 'consonant writing') and a generally telegraphic style have usually been interpreted as a response to the limited number of characters (max. 160) per message, and the small and awkward keyboard. They have since developed into a characteristic feature of the genre. It is not yet clear how technological innovations, such as predictive text software (which 'guesses' words after only a few key strokes), and market-related changes, such as the introduction of flat rates (rather than charging users per character), have affected (and will affect) the language of texting.

The Meanings of LOL: Semantic–Pragmatic Change in Electronic Communication

A well-known type of semantic–pragmatic change is subjectification, that is, the overall tendency for speakers/writers to construct new meanings on the basis of conversational implicatures reflecting speaker attitude or intention (cf. Traugott, 2000). In Internet Relay Chat (IRC), subjectification of meaning can be observed in the case of the popular abbreviation LOL/lol. The original propositional meaning of LOL is 'laughing out loud' and as such it can be used in response to, for example, a successful joke or an amusing story. This usage is indicated by metalinguistic comments such as 'I type it in after something funny is said . . . and I am laughing.' However, LOL, which has the structural advantage of shortness (i.e., it can be typed quickly), has been recruited and conventionalized by IRC users to express a range of discursive and interpersonal meanings (on laughter as a contextualization cue in spoken conversations; cf. Adelswärd and Öberg, 1998).

(1) LOL can be used as a discourse marker. This usage is illustrated in Example 1 (from a German chatroom, #Berlin), where <mib> closes his turn (a factual question addressed to another participant) with LOL, inviting a response from the addressee. The meaning of LOL in this example can be glossed as 'I have finished my turn, please answer my question.' (The spelling in Examples 1–4 is that of the original transcript and has not been corrected by the author of this paper.)

Example 1: #Berlin (8/7/2002)
<mib> kommst du eigendlich zum rl-treffen? ('will you come to the rl ('real-life')-meeting')
<mib> lol

(2) LOL can also be used as a supportive backchannel and as a means of establishing rapport between participants (emoticons can take on similar pragmatic and interactional meanings; cf. Crystal, 2001: 38). The following extracts come from two South African chatrooms (#Afrikaans; #India) and a German chatroom (#Berlin). In Example 2, <perfume_girl> uses LOL as an interpersonal modifier to soften her rejection of <Pyro>; her use of LOL fulfills pragmatic functions of hedging and face-saving. In Example 3, LOL is used in the context of

a virtual drinking game. It functions as an emphatic textual marker and creates emotional and interactional coherence (cf. Herring, 1999). In Example 4, <toxisches ei> ('toxic egg') uses LOL (as well as a positive emoticon) in response to the comment by <|Phylax|schule|>. The use of LOL is followed by supportive spoken-language discourse markers (*naja, hmm*).

Example 2: #Afrikaans (8/7/2002)
[1] <perfume_girl> sorry oom ('uncle')
[2] <perfume_girl> better luck next time
[3] <perfume_girl> lol
[3] <Pyro> ek is skat ry ('I am super rich')
[3] <perfume_girl> if u know what i mean
[4] <Pyro> help dit? ('does this help')
[5] <perfume_girl> lol
[6] <perfume_girl> nee ('no')
[7] <perfume_girl> sorry
[8] <Pyro> damnit

Example 3: #India (26/7/2002)
[1] <Renzo_ReXXXeL> what did he say?
[2] <PsYcHoMiKe> ehehe
[3] <MizHOttie> lets drink!
[4] <Miz_KeWL> LOL!
[5] * Miz_KeWL downs it!
[6] <MizHOttie> LOL!
[7] <MizHOttie> lol, wat he say

Example 4: #Berlin (19/8/2002)
[1] <|Phylax|schule|> beio uns ist der gk deutsch scwerer als der lk deutsch ('here (at our school) O-level German is more difficult than A-level German')
[2] <toxisches_ei> lol :D
[3] <toxisches_ei> naja
[4] <toxisches_ei> hmm

In the examples given above, LOL no longer has a clear propositional meaning. It appears to be 'desemanticized' or 'bleached' and is used as an interactional device that allows individuals to claim the floor, to express a range of interpersonal meanings (hedging, face-saving), and to provide supportive back-channeling and textual cohesion in the ongoing conversation.

(3) LOL can also occur as an adverb (expressing connotations of affection; cf. Example 4) and has developed a number of variants (*lolol, lolololo, lölchen* 'little lol' in German chats, *ol, olo*).

Example 5: #Berlin (17/7/2002)
<[c]hrono> mib du bist so lol :) ('mib you are so lol')

(4) Finally, the propositional meaning of LOL is increasingly and creatively deconstructed by Internet users, and a range of alternative meanings have been promoted in various on-line forums: 'lists of links,' 'lots of love,' 'lots of luck,' 'love on-line,' 'little old lady,' 'lovingly ornamented long-johns,' 'leagues of lemmings,' 'love of libraries,' etc.

Conclusion: Diversity of Usages

There is a constant tension between global and local practices in electronic media, and although the influence of, in particular, American English is paramount, local usages and variations persist (Danet and Herring, 2003). This refers not only to the large numbers of non-English-speaking Internet users who have developed their own jargons and usages, but also to those who do not participate fully in the subcultural linguistic practices of Netspeak. The degree to which individual users employ the innovative vocabulary of Netspeak and other highly marked in-group writing practices (e.g., consonant writing, emoticons, and abbreviations such as LOL) depends not only on the degree of their integration into the virtual speech community (Paolillo, 1999), but also on the genre (e.g., business e-mail vs. IRC) and the identity they wish to project within a particular communicative context (cf. also Crystal, 2001 on differences in language use across various 'Internet situations').

Semantic Change: Bleaching, Strengthening, Narrowing, Extension

E C Traugott, Palo Alto, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Like most terms in historical linguistics, 'semantic change' has been used to refer to both processes and results. Depending on the researcher's view of semantics, it has also been used to denote changes either in reference to the external world (object, cultural norms, etc.) or in a linguistic-internal sense, including ways in which pragmatic implicatures and inferences may become semanticized (coded) over time. Of all areas of linguistic change, semantic change is most subject to public comment and prescriptive attention. This is partly because semantics is codified in dictionaries, partly because of the ostensibly referential properties of some words, and most especially because meaning is subject to preemption by particular interest groups (cf. claims to the meaning of *Yankee* and, more recently to *gay* and *terror*) and even legislation (cf. the recent definitions of *harassment* as including 'hostile work environment').

Although in the past semantic change was often considered unsystematic, recent work has suggested that significant systematicities and unidirectionalities can be identified, especially crosslinguistically. These are usually considered from one of two complementary and mutually informing perspectives. The semasiological approach takes the form (hereafter *f*) as constant, ignoring phonological and other changes, and focuses on shifts in the senses associated with *f* (e.g., from *grasp* 'clutch' to 'understand'). The onomasiological approach takes abstract things or concepts as constant and focuses on recruitment to or loss of *f*s from the domain; for example, UNDERSTAND has come to be expressed by *grasp, understand*, and *comprehend* (itself ultimately derived from Latin *prehend*-'seize'). (Note: It is customary to represent abstract meanings in capitals, as in the previous example.)

Sometimes semantic change is treated as equivalent to lexical change. However, the latter concerns word formation, borrowing, and a number of morphological and phonological factors in addition to semantic change and will not be considered here.

Categories of Semantic Change

Early work on semantic change (e.g., Bréal, 1900/1966; Stern, 1931/1968; Ullmann, 1957) identified a recognized standard set of categories of change. The six listed next are the most important. (The following abbreviations are used: > means 'becomes' or, better, 'is assigned the new meaning' because the language itself does not change but, rather, speakers and hearers use languages in different ways over time;

Semantic Change: Bleaching, Strengthening, Narrowing, Extension

E C Traugott, Palo Alto, CA, USA

Introduction

Like most terms in historical linguistics, 'semantic change' has been used to refer to both processes and results. Depending on the researcher's view of semantics, it has also been used to denote changes either in reference to the external world (object, cultural norms, etc.) or in a linguistic-internal sense, including ways in which pragmatic implicatures and inferences may become semanticized (coded) over time. Of all areas of linguistic change, semantic change is most subject to public comment and prescriptive attention. This is partly because semantics is codified in dictionaries, partly because of the ostensibly referential properties of some words, and most especially because meaning is subject to preemption by particular interest groups (cf. claims to the meaning of *Yankee* and, more recently to *gay* and *terror*) and even legislation (cf. the recent definitions of *harassment* as including 'hostile work environment').

Although in the past semantic change was often considered unsystematic, recent work has suggested that significant systematicities and unidirectionalities can be identified, especially crosslinguistically. These are usually considered from one of two complementary and mutually informing perspectives. The semasiological approach takes the form (hereafter *f*) as constant, ignoring phonological and other changes, and focuses on shifts in the senses associated with *f* (e.g., from *grasp* 'clutch' to 'understand'). The onomasiological approach takes abstract things or concepts as constant and focuses on recruitment to or loss of *f*s from the domain; for example, UNDERSTAND has come to be expressed by *grasp, understand*, and *comprehend* (itself ultimately derived from Latin *prehend*-'seize'). (Note: It is customary to represent abstract meanings in capitals, as in the previous example.)

Sometimes semantic change is treated as equivalent to lexical change. However, the latter concerns word formation, borrowing, and a number of morphological and phonological factors in addition to semantic change and will not be considered here.

Categories of Semantic Change

Early work on semantic change (e.g., Bréal, 1900/1966; Stern, 1931/1968; Ullmann, 1957) identified a recognized standard set of categories of change. The six listed next are the most important. (The following abbreviations are used: > means 'becomes' or, better, 'is assigned the new meaning' because the language itself does not change but, rather, speakers and hearers use languages in different ways over time;

Chin. = (Mandarin) Chinese; Fr. = French; Gk. = Greek; Lat. = Latin; ME = Middle English (c. 1150–1500); OE = Old English (c. 600–1150); Span. = Spanish.)

1. Broadening (also referred to as generalization or extension): A relatively restricted meaning becomes less restricted, for example, Lat. *arripare* 'to arrive at the shore' > *arrive*; Late OE *docga* 'dog of a powerful breed' > generic *dog*.
2. Narrowing (also referred to as restriction or specialization): A relatively general meaning becomes more specific, for example, OE *deor* 'animal' > *deer*; OE *hund* 'generic dog' > 'hunting dog.'
3. Amelioration (also referred to as melioration): Meanings become more positive, for example, Lat. *nescius* 'ignorant' > *nice*; *Yankee* (from prior use as a derisive term).
4. Pejoration: Meanings become more negative, for example, OE *selig* 'blessed' > *silly*; ME *huswif* 'house-wife' > *hussy*; *knowing* 'having knowledge' > 'suggestive of secret knowledge' (cf. *a knowing look*); ME *cunning* 'knowledge, erudition' > 'deceitfulness,' ME *cur* 'dog' > a term of contempt (for dogs and humans).
5. Metaphor: One concept is transferred, projected or 'mapped' onto another that is in a different conceptual domain but has some resemblance to it, for example, Middle Fr. *grue* 'crane [bird]) > 'prostitute'; Lat. *musculus* 'little mouse' > 'muscle'; SPACE > TIME as in *before* 'in front' > 'earlier.'
6. Metonymy: One word is associated with another along the lines of already existing connections. Often-cited examples involve reference to perceived nonlinguistic contiguities, for example, the material that the object is made of for the object as in Gk. *papyrus* 'papyrus plant' (used as material for writing on) > *paper*; the form for the function as in OE *feoh* 'cattle' (used as payment) > *fee*; cause for effect as in *prove* 'test' > 'establish truth of'; and color for a plant associated with it as in 'the fruit of the orange tree' > *orange* 'color.' Metonymy is, however, also used with reference to language-internal associations, including ellipsis, for example, Fr. *rien* 'nothing' (from Lat. *res* 'thing,' typically used in the context of *ne* 'not'). Part for whole (synecdoche), as in *hands* 'laborers' and Span. *braceros* 'laborers' from *brazo* 'arm,' is sometimes treated as a subtype of metonymy and sometimes treated as separate from both metaphor and metonymy.

Because all six categories refer to both processes and results of change, it would be best to use forms derived with *-ation* for the last two, that is, 'metaphorization' and 'metonymization.' The six are discussed in this article in terms of how they have been construed from the perspectives of (1) semantic fields and Cognitive Linguistics, including Prototype Theory; (2) Neo-Gricean pragmatics, including Inviting Inferencing Theory; and (3) Grammaticalization Theory. For a history of early work on semantic change see Nerlich (1992), and for a brief partial account of more recent developments, see Traugott and Dasher (2002).

Although the pairs of changes that occur in the six types of semantic change may seem contradictory, they establish that later meanings of a form are linked to earlier ones; an arbitrary shift that breaks continuity of meaning is excluded. They also imply that change results from the use of language in context. Sometimes the context is cultural (value judgments about certain qualities, groups of people, etc., as with *hussy, silly,* and *nice*); sometimes it is linguistic (e.g., *rien*). Many words can be shown to have undergone several semantic changes over time. For example, originally Fr. *bureau* was borrowed into English to refer to a woolen cloth covering tables; by metonymization it came to be used for the furniture under the cloth, and by specialization it came to be used for desks; later it was generalized metonymically to offices with several desks and then to the function of those offices. Likewise, Fr. *toilet* was borrowed meaning 'a cloth for wrapping,' restricted to 'a cloth covering a dressing table,' metonymized to the table and to dressing at it (cf. *do one's toilet*), and finally used euphemistically for *lavatory*. Sometimes different changes occur in different syntactic functions. For example, OE *prættig* 'crafty, deceitful' came by metonymic association with artfully devised appearances to be ameliorated as 'handsome'; by narrowing it came to be associated largely with children and females; used as an adverb meaning 'in a fair way' it came by broadening (and ultimately bleaching) to mean *very* (cf. *that's pretty ugly*). Many metonymic pejorations can be seen to result from euphemism and taboo, in which case they are called 'dysphemisms.' Smells are often associated with objectionable experiences. This accounts for the pejoration of *stink* (originally OE *stincan* 'to smell (sweet)') and even of the word that replaced it, *smell*; this in turn is being replaced by *odor* and *scent* (the movie title *Scent of a Woman* would have had an entirely different connotation if *smell* or even *odor* had been used). Note that although the pejoration of *smell* is semasiological, its substitution by another word (*scent*) is onomasiological. A similar example is *undertaker* (originally 'someone who undertakes a job'), which by specialization, and hence pejoration, > 'funeral director'; in this meaning, *undertaker* has been replaced by *mortician* (borrowed terms are often considered

at least initially to be neutral, but they may then undergo semantic change).

All semantic change arises by polysemy; that is, new meanings coexist with earlier ones, typically in restricted contexts. Sometimes these new meanings split off and are no longer conceptualized as variants; for example, *mistress* used to mean 'woman in a position of authority, head of household,' but it came to be pejorated as 'woman in a sexual relation to a man.' The original meaning still survives but largely in restricted contexts (*mistress of the household, school mistress*). Most people nowadays probably think of the meaning in these phrase as distinct (homonymous).

Notations such as *stincan* 'smell (sweet)' > *stink* 'smell bad' not only suggest that the older meaning was replaced rather than being in a polysemous relation to the newer one but also that the change was instantaneous. In reality, the old and the new meaning typically coexist for a long time, at least in different communities and in different text types (e.g., conversation on the job, letters, drama, legal language, and poetry). For example, ME *estate* originally meant 'condition, status' and then, in legal contexts, 'interest in property including land'; only in the 18th century did it come to be used primarily for buildings (of the landed gentry). The original meaning persists but is largely restricted nowadays to religious and philosophical contexts, and the property meaning is largely restricted nowadays to legal ones (except in phrases such as *housing estate, real estate*).

From the Perspective of Semantic Fields, Cognitive Linguistics, and Prototype Theory

As attention turned during the 20th century from reference to sense and to relationships between abstract meanings, categories of change took back stage to the study of 'semantic fields': abstract meaning relationships that hold between sets of words and how they change over time (see Gordon, 2001, for early work). Some of these studies identified unidirectional changes. For example, Stern (1931/1968) noted that English words meaning RAPIDLY (e.g., OE *swifte* 'swiftly') came in the context of perfective verbs to mean IMMEDIATELY before 1300 but not later and suggested that semantic change was subject to 'laws' similar to those in phonology. Because 'laws' were, by hypothesis, exceptionless, but semantic change is not, this particular suggestion was problematic, but the observation of directionality proved to be highly fruitful because it drew attention to systematicities of change. Work was conducted in domains such as color (Kay, 1975); perception (Viberg, 1983); and synesthesia, the metaphorical extension of terms for the five senses into the domain of other sense and social behaviors, language, and so on (e.g., *soft sound* and *bitter comment*) (Viberg, 1983). This work suggested that terms for touch are extended cross-linguistically to hearing and sight and that terms for taste are extended to smell and sound, but not vice versa, so we would not expect *sweet touch*. In a study of metaphorization in the lexical field of English animal names, Lehrer (1985) showed that many came to be used pejoratively in the 15th and 16th centuries; for example, terms for primates, birds, and scavenger birds came to be used to signal brutishness, foolishness, and greed, respectively (e.g., *baboon, pigeon,* and *vulture*).

Metaphorical extension of meaning came to play a central role in Cognitive Linguistics, in which abstract meanings are interpreted as cognitive schemas, scenes, and frames. In a book that proved seminal for later work on semantic change, Sweetser (1990) suggested that one way to conceptualize the synchronic polysemic relationship between verbs of perception and cognitive states (cf. *I hear you* 'I understand you') or of root (obligation, or 'deontic') and epistemic (inferential) modality is in terms of metaphorical mapping of image schemata. Building on aspects of Talmy's (1988) theory of force dynamics, she hypothesized that the *may* of permission (*Kim may leave; I allow it*) expresses "an absent potential barrier in the sociophysical world," and epistemic *may* (*Kim may be there*) "is the force-dynamically parallel case in the world of reasoning" (Sweetser, 1990: 59). Root *must* (*you must go*) indicates a real-world force that compels the subject to act, whereas epistemic *must* (*you must be tired*) indicates that "an epistemic force applied by some body of premises" compels the speaker to "reach the conclusion embodied in the sentence" (Sweetser, 1990: 64). Seeking to account for the abstract patterns of thought underlying regular tendencies of change, she argued that meaning change in the modals is a unidirectional metaphorical mapping from content > reasoning meanings, not vice versa, because "viewing X as Y is not the same as, and does not imply, viewing Y as X" and metaphorical mapping is "inherently unidirectional" (Sweetser, 1990: 19).

A basic assumption of Cognitive Linguistics is that meanings are not discrete but overlapping. They are prototypical and some representations are more central ('stereotypical' or 'salient') than others. Furthermore, there are often "clusters of overlapping and interlocking meanings" (Geeraerts, 1997: 61). From the perspective of prototype theory, broadening and narrowing can be seen as the result of metaphorization and metonymization. The key issue is change in

the saliency of a meaning; for example, the salient meaning of the brand-named container known as *Thermos* came to be generalized to all vacuum containers designed to keep liquids hot or cold; the salient meaning of *liquor* 'generic liquid' came to be narrowed to 'alcoholic liquid'; and *meat* 'generic food' came to be 'food from animals.' Geeraerts (1997) provided a detailed account of historical prototype semantics, and Eckardt (2001a) formalized it in terms of Montague semantics.

From the Perspective of Neo-Gricean Pragmatics and Invited Inferencing Theory

Another strand of work has highlighted ways in which pragmatic polysemies can become coded as semantic polysemies (see e.g., Horn, 1984; Levinson, 2000; Enfield, 2003). Building on Levinson's (2000) revival of Grice's distinction among (1) utterance token implicatures that are by hypothesis universal and arise on the fly in the context of strategic interaction between speaker and hearers (and writers and readers), (2) utterance type implicatures that are conventionalized in particular communities and languages, and (3) coded meanings that are conventions of a language at a given time, Traugott and Dasher (2002) developed the Invited Inferencing Theory of Semantic Change. According to this model, utterance token implicatures may become salient and normative types in a community; at this point, meanings may be indeterminate or ambiguous. Change occurs when these utterance type implicatures are semanticized, that is, when the earlier meaning of an item would not make sense in a particular utterance (the earlier type implicature has been reanalyzed as a distinct meaning of *f*). The inference may, of course, not always be semanticized and may persist for centuries, even millennia (cf. *after*, the causal implicature of which has not been semanticized). Enfield (2003: 29) referred to ambiguous or indeterminate utterances at the intermediate stage as "bridging contexts"; here "an interpretation of *f* as merely implicating 'q' (on the basis of 'p') or as actually meaning 'q' (as distinct from 'p') become functionally equivalent."

The term 'invited inferencing' is used to highlight the fact that change occurs in strategic interaction: Speakers/writers invite hearers/readers to infer meanings beyond what is said. It is an associative process in the syntagmatic flow of speech and, therefore, has much in common with metonymy. Metonymy has, however, often been restricted to language-external associations (e.g., *paper, fee, orange,* and *bureau*). By contrast, invited inferencing is strictly language-internal, conceptual metonymy.

One recently much discussed type of semantic change is 'subjectification.' Langacker (1990) restricted subjectification to changes in the interpretation of the syntactic subject characteristic of raising constructions, for example, the shift from the restriction to animate subjects in motion in *be going to* or in the speech act verb *promise* constructions to the availability of inanimate or expletive subjects in future/epistemic constructions (*there is going to be an earthquake; it promises to be a fine day*). However, subjectification can be more broadly construed as a metonymically based association of what is said to the speaker's attitudes and speech act purposes by which speakers and writers recruit meanings to express and to regulate beliefs, attitudes, and so on (Traugott and Dasher, 2002; Traugott, 2003). At the most basic level, subjectification encompasses the evaluative, emotive changes known as amelioration and pejoration (cf. *silly* and *nice*) and euphemism (*scent*). But it also encompasses shifts from obligation to epistemic attitude, whether or not raising occurs, for example, *actually* 'in the act' > 'in reality,' as well as *promise* 'oblige/commit oneself to' > 'be likely to.' Subjectification also includes shifts from concrete descriptive meanings to focus particles and discourse connectives, for example, *only* 'single' (*an only child*) > 'focus particle' (*only Jane left*) > 'dismissive discourse connective' (*they are lovely*; *only, they have thorns*) (Brinton, 1998), as well as shifts from ultimately spatial terms to performative verbs (Lat. *pro-miss-* 'forward-sent' > *promise*).

The influence of Gricean pragmatics is particularly apparent in Horn (1984). Horn associated the Second Maxim of Quantity, Relation and Manner (Make your contribution necessary. Say no more than you must; he calls this the 'R-Principle') with semantic broadening (cf. *thermos*). Here, the specific term is understood to represent a salient exemplar of a wider class (Horn, 1984: 35). In Horn's view, the R-Principle may also give rise to narrowing, as in the case of a shift from set to subset (hyponym) denotation; that is, "a delimitation of a general term to a sense representing a salient exemplar of the category denoted by that term" (Horn, 1984: 35), as in *undertaker* and *liquor.* But narrowing may also involve what Horn called the Q-Principle, which combines Grice's First Maxim of Quantity and Relation (Make your contribution sufficient. Say as much as you can.). For example, a superordinate term in a taxonomy (e.g., *finger, gay*) may be narrowed to exclude its complement; when we say *I hurt my finger*, this is understood to exclude the thumb, and *they are gay* can be understood to exclude lesbians. In this view, the specialization of the general term is "triggered by the prior existence of the hyponym of that term" (Horn,

1984: 35), a situation called 'autohyponymy.' As Horn points out, autohyponymy is very idiosyncratic historically.

Although there is a great deal of mutual influence between Cognitive Linguistics and Neo-Gricean pragmatics in work on historical semantics, the emphasis is rather different in each theoretical tradition. The prime focus on metaphorization and metonymization in Cognitive Linguistics is on the cognitive structuring that they reveal. In Neo-Gricean pragmatics, it is on communicative strategizing as well as cognitive structuring. Furthermore, metaphorizing has played a stronger role in Cognitive Linguistics, whereas conceptual metonymization has played a stronger role in Neo-Gricean pragmatics.

From the Perspective of Work on Grammaticalization Theory

Much work on grammaticalization, "the change whereby lexical items and constructions come in certain linguistic contexts to serve grammatical functions, and once grammaticalized, continue to develop new grammatical functions" (Hopper and Traugott, 2003: 18), has focused on crosslinguistic typologies of semantic change as they interact with, and indeed in many cases trigger, morphosyntactic change (see Bybee *et al.*, 1994; Haspelmath, 1997; Heine and Kuteva, 2002). Standard examples include SPACE > TIME, for example, *before* 'in front' > 'earlier'; *be going to* 'be in motion toward' > 'future' OBLIGATION > EPISTEMIC, for example, *must* 'obligation' > 'conclusion'; GIVE > dative case adpositions, for example, Chin. *gei* 'give' > 'to.'

Grammaticalization has been construed as arising primarily from metaphorical conceptualization, specifically mapping of a more concrete concept onto a more abstract one (e.g., Heine *et al.*, 1991). However, arguing that what appears to be metaphorizing is in most cases an artifact of citing examples out of context and is, in fact, usually the result of implicatures that arise associatively (metonymically) in highly specific linguistic contexts. Bybee *et al.* (1994) and Traugott and Hopper (2003) showed that grammaticalization arises not so much out of metaphorical processes but primarily out of conceptual metonymy and invited inferencing. Texts typically reveal extensive evidence of bridging contexts at periods of transition. This suggests that, for example, *must* was not directly assigned an epistemic meaning by the mapping of obligation in the physical world onto obligation in the world of reason, as Sweetser's metaphorical model would suggest. Rather, the implication that the individual who is obliged to do something will do it became salient over time, especially in contexts in which the obligation was imposed by God or a king. Once the change has occurred, synchronically the relationships between obligation and conclusion may appear to be metaphorical, but the historical process is metonymic.

A word or lexical item can undergo grammaticalization only if it has a very general meaning and one relevant to grammatical structure; thus, *thing* is susceptible to interpretation as a pronoun, whereas *desktop* is not; likewise, *go* and *come* are interpretable as markers of temporality (especially tense) but *creep, jump,* and *drive* are not. Sometimes the contentful meaning of a word may become weaker over time, allowing it then to be subject to grammaticalization (e.g., Lat. *ambulare* 'to walk,' which was generalized to motion in general before its descendant Fr. *aller* 'to go' became available as a marker of future). Meanings are often said to be weakened, 'desemanticized,' or 'bleached' during grammaticalization. It is true that they lose concrete, referential, and content meaning and become highly abstract, but they normally do not become devoid of meaning, as 'bleaching' suggests (an exception is the *do* that is automatically required in a question as in *did you see that*?). On the contrary, in the course of grammaticalization, a former nonreferential implicature typically becomes enriched or strengthened (Sweetser, 1988). In many cases, these grammatical meanings are indexical, for example, personal and demonstrative pronouns (Span. *vuestra merced* 'your grace' > *usted* 'second-person singular polite'), scalar focus particles *(mere* 'pure, absolute' > 'nothing more than'; see König, 1991) and discourse markers (*in fact, y'know*; see Brinton, 1996). Sometimes bleaching is identified with grammaticalization. However, bleaching also occurs in the lexicon; a number of terms are used as address forms (e.g., *love* and *kiddo*), and recently the slang word for 'feces' has come to be used to mean 'stuff' (*I've got a lot of shit to do*) (note the pragmatically negative connotation, arising from association with the dysphemistic source). Eventually, such bleached forms might become grammaticalized as pronouns, but that would require them to be analogized with other pronouns, that is, made to share their distributional properties.

The term generalization (also broadening) is sometimes used synonymously with bleaching. It is, however, important to distinguish bleaching, although the latter may arise from generalization (cf. the development of degree *pretty*). Terms that broaden or generalize become hypernyms, higher, more abstract members of a semantic hierarchy. When *dog* came to be used in ME as the generic term it was generalized (it came to refer to a larger set of canines). This is not bleaching; however, use of *dog*

in, for example, *you dog*! (associated with an exclamatory intonation pattern) is – the content meaning 'canine' has been lost or at least demoted, and what is salient is the evaluative, insulting meaning of the construction.

Most examples of grammaticalization involve subjectification because speakers innovate grammatical meanings precisely to mark their perspective on what is said: what role the participants have in an event (case marking, raising), when the event occurred with respect to some other time (tense marking), what temporal perspective it had (completed, ongoing, etc.; aspect), how likely it was (modality), where the speaker got the information from (evidentiality), how the speaker perspectivizes the relationship between utterances (connectives, discourse markers), and what the focus of the speaker's contribution is (focus particles, topic markers). However, as previously indicated, subjectification is not limited to grammaticalization.

Constraints on Semantic Change

A number of constraints on semantic change have been proposed, of which three are mentioned here: semantic constraints on grammaticalization, avoidance of synonymy, and avoidance of homonymy.

1. Semantic constraints on grammaticalization. As we have seen, an item can undergo grammaticalization only if it has a very general meaning. Talmy (2000: 24–31) has, in addition, proposed that, synchronically, grammatical meanings tend to be related to topological, relativistic, and qualitative (and not Euclidean, absolute, or quantitative) meanings. Grammatical meanings do not express specific quantities (e.g., *inch* and *year*) or specific geometric relations (e.g., *square* and *corner*). Therefore, by hypothesis, Euclidean geometric terms are unlikely to be grammaticalized; that is, they are much less likely to be bleached of semantic content and enriched with grammatical meaning in the way that topological ones are, for example, *head* (cf. *in the years ahead* 'in future years') and *side* (cf. connective *besides*).
2. Avoidance of synonymy. Rather than using both *dog* and *hound* as the generic term for canines, speakers of ME shifted the semantic labor between the terms essentially by reversing their genericity. When a synonymous word is borrowed, a division of labor typically occurs; famous examples include native *cow*, used for the animal, and borrowed *beef*, used for the meat of the cow; likewise, native *sheep* and *pig*, versus French-derived *mutton* and *pork* (initially, at least, the borrowed word was associated with elite cuisine).
3. Avoidance of homonymy ('homonymiphobia'; see Geeraerts, 1997). There is a supposed constraint against development of homonyms with meanings that might be confused, especially those that are antonymous. Well-known examples are the development by sound change of both Lat. *cattus* 'cat' and *gallus* 'rooster' into southwestern Fr. *gat* and of both OE *lætan* 'permit' and *lettan* 'prevent' into ME *let*. The 'rooster' and 'prevent' meanings came to be expressed by other words: *gat* 'rooster' came to be referred to as *bigey*, a local variant of *vicaire* 'curate' (creating a new ambiguity), whereas *let* 'prevent' came to be referred to by native *forbid* and borrowed *prevent*. However, in fact, the coexistence of forms with apparently contradictory meanings is quite common, as evidenced by 'enantiosemy,' the presence of polysemies in which one sense is in some respect the opposite of the other. For example, *dust* can mean 'remove' or 'add,' but usually not in the same context (cf. *I dusted the table* 'removed dust from' and *I dusted the strawberries with sugar* 'added sugar to the top of'). The verb *sanction* can mean 'approve' or 'penalize' (e.g., for someone ignorant of current affairs, the headline *Bush sanctions Iran* could be understood in opposite ways). Eventually, enantiosemies do seem to be resolved, but this may take centuries. In English, adverbial expressions may be used (e.g., *rent to/rent out*); or there may be semantic split (often in different communities), for example, Lat. *populare* 'to devastate' appears later as Span. *poblar* 'to settle, colonize' and Eng. *populate*; also Indo-European **ghos-ti* 'stranger,' which gave rise to *guest, host,* and *hospital* but also to *hostile*. Antonymous homonyms and polysemies are puzzling to those who think in terms of discrete meanings out of context. They are not puzzling from the perspective of overlapping prototype meanings that arise and are maintained in different contexts.

Conclusion

Ultimately, the only ways of innovating meaning are metaphorization and metonymization. "The trick of being innovative and at the same time understandable is to use words in a novel way the meaning of which is self-evident. But there are only two main ways of going about that: using words for the near neighbours of the things you mean (metonymy) or using words for the look-alikes (resemblars) of what you mean (metaphor)" (Nerlich and Clarke, 1992: 137). From this perspective, it is not surprising to find that the dominant type of semantic change is subjectification: the metonymic use of words to express one's

evaluative viewpoint and to acknowledge (however unconsciously) the salience of speaker–hearer interaction, the most immediate neighbor to the communicative situation. Synchronically, metonymies can be regarded as indexical and syntagmatic, whereas metaphors can be regarded as paradigmatic. Diachronically, both types of innovation involve analogized inferences about similarities, whether to near neighbors in metonymy or to more distant resemblars in metaphorization. Semanticization of both types of innovation involves the reanalysis of the semantic content of *f* (for a proposal about how to formalize semantic reanalysis, see Eckardt, 2001b).

Meanings can also be borrowed, either with the foreign form, or calqued (translated into native forms with roughly equivalent meanings). Typically, meanings are borrowed without their original cultural associations. Therefore, the borrowed meaning may only approximate the original (e.g., *weltanschauung* and *sushi*). Like all borrowings, borrowed meanings are subject to change in the adopting language; for example, *feng shui* (originally Mandarin Chin. *feng* 'wind' + *shui* 'water,' used to refer to the practice of positioning objects such as graves, buildings, and furniture according to the principles of the opposing effects of ying and yang) has been generalized to 'cause to be in a peaceful state of mind' (cf. *fengshui your commute*). In sum, semantic change is subject to the same three mechanisms of change as morphosyntax: analogy/extension, reanalysis, and borrowing (Harris and Campbell, 1995).

Semantic Maps

J van der Auwera and C Temürcü, University of Antwerp, Antwerp, Belgium

A semantic map is a technique that aims to represent sound–meaning correspondences. It links up language-specific formal categories, henceforth 'markers,' to semantic categories, henceforth 'uses.' The essential idea is that multiple uses of a marker are related in a systematic and universal way. Consider the main strategies which English uses to refer to a nongeneric indefinite human being (1–9).

(1) **Somebody** called you while you were away: guess who?

(2) I heard **somebody**, but I couldn't tell you who.

(3) Please ask **somebody** else.

(4a) If you see **somebody**, tell me immediately.
(b) If you see **anybody**, tell me immediately.

(5a) Did **somebody** tell you about it?
(b) Did **anybody** tell you about it?

(6) He is better than **anybody** else in the group.

(7) I don't think that **anybody** knows the answer.

(8) **Anybody** can solve this problem.

(9a) I haven't seen **anybody**.
(b) I have seen **nobody**.

(1) to (9) list the nine uses that Haspelmath (1997) distinguished in a typological study of indefinite pronouns. As far as English is concerned, there are three main strategies: *somebody* (or *someone*) is used in (1–5), *anybody* in (4–9), and *nobody* in (9). Italian, too, has three main strategies, but they do not distribute along the lines of English. In the Italian translations, one will find *qualcuno* in (1–5, 7), *chiunque* in (6, 8), and *nessuno* in (5, 7, 9) (Haspelmath, 1997: 262–263). Haspelmath (1997) studied some 140 languages and found a great deal of variation, with respect to both the number of markers and their distribution. But there is also unity in this diversity. First, all the languages map their strategies on the same 'semantic space'. This semantic space is shown in (10). The map has nine points, each of which can be identified on semantic grounds. The labels are the ones proposed by Haspelmath (1997) and the numbers correspond to the example sentences (1–9). The lines show how the uses are related to each other. The second similarity concerns the fact that each marker covers a contiguous area. In (11) and (12) the uses of each of the markers are represented as an overlay. (11) shows the mapping needed for English, and (12) is the one for Italian.

The semantic map perspective is not entirely new. It relates to earlier work on semantic fields (e.g., Trier,

A semantic map is a technique that aims to represent sound–meaning correspondences. It links up language-specific formal categories, henceforth 'markers,' to semantic categories, henceforth 'uses.' The essential idea is that multiple uses of a marker are related in a systematic and universal way. Consider the main strategies which English uses to refer to a nongeneric indefinite human being (1–9).

(1) **Somebody** called you while you were away: guess who?

(2) I heard **somebody**, but I couldn't tell you who.

(3) Please ask **somebody** else.

(4a) If you see **somebody**, tell me immediately.
(b) If you see **anybody**, tell me immediately.

(5a) Did **somebody** tell you about it?
(b) Did **anybody** tell you about it?

(6) He is better than **anybody** else in the group.

(7) I don't think that **anybody** knows the answer.

(8) **Anybody** can solve this problem.

(9a) I haven't seen **anybody**.
(b) I have seen **nobody**.

(1) to (9) list the nine uses that Haspelmath (1997) distinguished in a typological study of indefinite pronouns. As far as English is concerned, there are three main strategies: *somebody* (or *someone*) is used in (1–5), *anybody* in (4–9), and *nobody* in (9). Italian, too, has three main strategies, but they do not distribute along the lines of English. In the Italian translations, one will find *qualcuno* in (1–5, 7), *chiunque* in (6, 8), and *nessuno* in (5, 7, 9) (Haspelmath, 1997: 262–263). Haspelmath (1997) studied some 140 languages and found a great deal of variation, with respect to both the number of markers and their distribution. But there is also unity in this diversity. First, all the languages map their strategies on the same 'semantic space'. This semantic space is shown in (10). The map has nine points, each of which can be identified on semantic grounds. The labels are the ones proposed by Haspelmath (1997) and the numbers correspond to the example sentences (1–9). The lines show how the uses are related to each other. The second similarity concerns the fact that each marker covers a contiguous area. In (11) and (12) the uses of each of the markers are represented as an overlay. (11) shows the mapping needed for English, and (12) is the one for Italian.

The semantic map perspective is not entirely new. It relates to earlier work on semantic fields (e.g., Trier,

(10)

(11)

(12)

1931) or semantic networks (e.g., Aitchison, 1994) and there is even a resemblance with classical geometrical representations such as the 'Aristotelian square' (van der Auwera, 1996). Map making such as shown in (10) to (12) has proved successful for a wide variety of linguistic phenomena, particularly in the typology of grammatical semantics. These phenomena include the perfect (Anderson, 1982 – the first semantic map study), reflexives and middles (Kemmer, 1993), intransitive predication (Stassen, 1997), modality (van der Auwera and Plungian, 1998), mood (van der Auwera *et al.*, 2004), semantic roles (Luraghi, 2001; Haspelmath, 2003), and coordination (Haspelmath, 2004). In Croft (2001), semantic maps have even become a key component of a grammatical model. Semantic maps are also called 'implicational' (Haspelmath, 1997), 'cognitive' (Kortmann, 1997), 'mental' (Anderson, 1982), or 'conceptual' (Croft, 2001, 2003); Croft (2001, 2003) preferred to call them 'spaces,' reserving the term 'map' for any marker-specific region of the semantic space. The maps are hypothesized to be universal, and for some linguists they are not merely linguistic but pertain to "deeper levels of conceptualization" (Kemmer, 2003: 90). In the words of Croft (2001: 364), they show the "geography of the human mind, which can be read in the facts of the world's languages in a way that the most advanced brain scanning techniques cannot ever offer us."

The predictive power of the contiguity requirement is considerable. Once a semantic map is arrived at, usually through a combination of deductive semantic analysis and inductive generalizations on a sufficiently large sample of languages, one can predict that if a newly discovered marker has two uses that figure on the map, either these uses will be adjacent or the marker will also have the uses that connect them. Suppose we know about a marker that it is used for direct negation as well as for specific known reference. Then we can expect that it is also used for indirect negation, irrealis nonspecific, and specific unknown, as well as question and/or comparative and, if comparative but not question, then necessarily also for conditional reference. (Swedish *någon* is an illustration of this kind of marker: it has all the uses, except for the free choice use.)

We cannot, however, exclude noncontiguity. First, noncontiguous markers are acceptable in cases where they are the remnants of a contiguous area in an earlier stage of the language. Turkish *biri*, for instance, now covers all uses from specific known to direct negation, through the upper layer, as well as conditional. It should not be excluded that new markers develop and push *biri* out of all uses except specific known and direct negation, two uses which are not directly related. In the case of Tense-aspect-mood (TAM) maps, this kind of noncontiguity has already been documented. A modality example comes from Dutch. *Mogen* 'may' has a use paraphrasable by 'like' (13). One will be hard pressed to posit a direct semantic link between this use and the optative or concessive ones in (14) and (15). It is more plausible to discuss them in terms of homonymy and to see them as connected via uses which are no longer allowed in the modern language (see van der Auwera, 1999; see also Haspelmath, 1998 for an example involving tense).

(13) Ik mag soep.
I may soup
'I like soup.'

(14) Lang mag hij leven.
Long may he live.
'Long may he live.'

(15) Het mag dan al groot zijn,
It may then already big be
mooi is het niet.
beautiful is it not.
'It may be big, but it is not beautiful'.

Second, one should not exclude that two markers with different etymologies (possibly even borrowings from other languages) coalesce formally and that their uses end up on one and the same semantic map. The semantic connections could be expected to make these markers develop the in-between uses as well, and thus turn the homonymy into a polysemy. But, especially if the markers enter the map in only distantly related corners, the semantic pressure may be low. A possible example is the suffix *-m* in the Trans-New Guinea language Kilmeri. It is part of the (circumfixal) coding of the prohibitive – with a prefix that marks anaphoricity – and all by itself it is also a marker of weak probability (Gerstner-Link, 2004: 249). The prohibitive mood is – or is related to – deontic modality, and weak probability is epistemic modality. So the two uses are indeed related. But the relation remains weak and it is far from obvious how an assertion that the hearer will perhaps do something can amount to a prohibition to do this. So we may in fact be dealing with homonymy.

The discussion of the two cases of noncontiguity made it clear that although semantic maps are designed to map similarity of meaning and thus invite interpreting the various uses as exemplifying either vagueness or polysemy, there is room also for homonymy. The idea is simple: the weaker the semantic link between any uses, especially also when the uses are not (no longer or not yet) contiguous, then the uses are more likely to count as homonymous. Whether or not any individual speaker recognizes or exploits the semantic links posited by the linguists is yet another matter (see Sandra and Rice, 1995).

As the discussion of noncontiguity already shows, semantic maps have both a synchronic and a diachronic dimension. The contiguity requirement, while providing a synchronic constraint on possible patterns of polyfunctionality, simultaneously shows the possible paths of change. In this way, the semantic map approach has been linked with grammaticalization theory. In this theory, one studies the development of grammatical uses (and markers) out of one another and ultimately out of lexical meanings (and lexical items). The changes happen along what have been called 'paths' (Bybee and Dahl, 1989), 'chains' (Heine *et al.*, 1991), 'clines' (Hopper and Traugott, 1993), and 'channels' (Lehmann, 1995), and these are nothing else than the lines of the semantic maps that have been given a direction: the lines have become arrows. One must, however, allow that the relevant markers are no longer fully identical for grammaticalization involves a formal change as well as a semantic change.

It is of interest that arrows are not the only notational device that can be used to 'enrich' maps. Thus van der Auwera and Plungian (1998) made some proposals to represent the nature of the semantic change. They used ovals instead of points to represent individual uses, and suggested representing semantic specialization and generalization as inclusion of ovals, and metonymic/metaphoric links as mere contiguity.

(16)

A final point is that semantic maps relate to the study of crosslinguistic gram types, as represented by Dahl (1985) and Bybee *et al.* (1994). Crosslinguistic gram types are idealized formal categories identified by a primary focal meaning and associated with a number of secondary foci. They are defined at a level "mediating between the universal concepts and the language-specific grams," which "singles out areas of the universal semantic space that are frequently grammaticalized across languages" (Bybee *et al.*, 1994: 48). From the semantic map perspective, the crosslinguistic gram types will involve those uses and combinations of uses that show up with a relatively high frequency. Given the example of the indefinite pronouns, a marker covering uses (2) and (3), and then, after the bifurcation, also the upper-layer uses (5), (7), and (9), would seem to be a candidate for a gram type status, given the data in Kahrel (1996: 37). A similar arrangement with (2) and (3), but with the lower-layer uses (4), (6), and (8) definitely is not: it is simply unattested (Haspelmath, 1997: 76–77). This illustration shows that semantic maps have their limitations: there is nothing in the semantic map itself that gives us any reason to expect the upper-layer arrangement to be more recurrent than the lower-layer one. But one can look at it in a different light: the semantic map represents the logical space of possible patterns of polyfunctionality, allowing for both the frequent and the infrequent and even the nonoccurring ones. As such, it provides the basis for further analysis.

Semantic Primitives

A Wierzbicka, Australian National University, Canberra, Australia

© 2006 Elsevier Ltd. All rights reserved.

The idea of semantic primitives (or primes) goes back to Leibniz's views that all human thoughts, no matter how complex, are constructed out of a set of elementary building blocks – simple concepts that are innate and the same for all people. He called this hypothetical set "the alphabet of human thoughts." In Leibniz's thought, the conviction that there must be such an innate set of simple concepts was linked with the idea that all explanations must ultimately rely on some simple concepts that are self-explanatory: without some such basic, self-explanatory concepts, all human explanations would be futile – one would always have to ask "and what do you mean by that?," *ad infinitum*.

> If nothing could be understood in itself nothing at all could ever be understood. Because what can only be understood via something else can be understood only

> to the extent to which that other thing can be understood, and so on; accordingly we can say that we have understood something only when we have broken it down into parts which can be understood in themselves (Leibniz, 1961: 430).

Other 17th-century philosophers also insisted that all complex ideas must be built from simple ones, and they drew from this the conclusion that not all words could be defined: an attempt to define all words would necessarily lead to an infinite regress. For example, Arnauld and Nicole (1996/[1662]: 64) wrote:

> I say it would be impossible to define every word. For in order to define a word it is necessary to use other words designating the idea that we want to connect to the word being defined. And if we then wished to define the words used to explain that word, we would need still others, and so on to infinity. Consequently, we necessarily have to stop at primitive terms which are undefined.

But if all explanations, and all definitions, must ultimately rely on a set of concepts that are self-explanatory, then it is crucial to identify those elementary, self-explanatory conceptual building blocks on which all human understanding depends. Leibniz thought that in principle this could be done by analyzing human languages, because languages are "the best mirror of the mind."

In the 20th century, the idea of searching for semantic (or conceptual) primitives through an analysis of meanings encoded in languages was taken up by a number of linguists. In particular, the Danish scholar Louis Hjelmslev (1969) initiated an approach that later came to be known as 'componential analysis.' For example, he proposed that the meaning of words like *ram*, *ewe*, *stallion*, *mare*, *man*, *woman*, *boy*, and *girl*, could be represented as a combination of elements like 'he,' and 'she,' 'sheep,' and 'horse,' 'human being,' and 'child.' Hjelmslev's ideas were later taken up and developed in new ways by linguists like Manfred Bierwisch (1967) and Jerrold Katz (1972).

But none of these scholars followed Leibniz's idea that the innate "alphabet of human thoughts" can be found through reductive paraphrases, that is, through definitions explaining complex meanings in terms of self-explanatory 'indefinibilia' (indefinables). This idea was first put on the agenda of modern linguistics by the Polish linguist Andrzej Bogusławski (1970), first in a lecture delivered at Warsaw University in 1964. Bogusławski maintained that the "golden dream" of the 17th-century thinkers, which could not be realized within the framework of philosophy and was therefore generally abandoned as utopian, could be realized if it was approached from a linguistic rather than from a purely philosophical point of view: the experience and achievements of modern linguistics (both empirical and theoretical) made it possible to approach the problem of conceptual primitives in a novel way and to put it on the agenda of an empirical science.

Leibniz's theory of an "alphabet of human thoughts" (1961: 435) could be dismissed as a utopia because he never proposed anything like a complete list of hypothetical primitives. As one modern commentator wrote, "in these circumstances it is understandable that Leibniz should consistently avoid the obvious question as to the number and type of fundamental concepts. The approach would be more convincing if one could at least gain some clue as to what the table of fundamental concepts might look like" (Martin, 1964: 25). Bogusławski argued that the best clues as to what the table of fundamental concepts might look like come from language, or, more precisely, from languages, and that for this reason linguistics had a chance of succeeding where philosophical speculation had failed. Unlike the proponents of 'componential analysis' based on 'features,' 'markers,' and other artificial devices, Bogusławski followed Leibniz in linking the idea of semantic primitives with the idea of 'reductive paraphrase,' formulated in, and intelligible through, ordinary language.

The 'reductive paraphrase' approach to the search for semantic primitives found a fuller programmatic expansion in the work of another Polish linguist, Anna Wierzbicka, whose book *Semantic primitives* (1972) proposed a first list of hypothetical semantic primes. That first list included only 14 elements: 'someone,' 'something,' 'I,' 'you,' 'world,' 'this,' 'want,' 'don't want,' 'feel,' 'think,' 'imagine,' 'say,' 'become,' 'be a part of.' After Wierzbicka's emigration to Australia (in 1972), the search for semantic primitives became increasingly linked with an empirical crosslinguistic search for lexical universals – words and wordlike elements that have exact semantic equivalents in all languages.

This major shift in the program from 'primes' to 'primes and universals' was associated with the theoretical and empirical input of the Australian linguist Cliff Goddard, and the evidence for or against hypothetical semantic primitives came to be increasingly drawn from Australian languages. (For example, 'world' and 'imagine' were removed from the original list in response to Goddard's observations on Australian languages.) The assumption behind the shift from 'primes' to 'primes and universals' was that if there are some innate simple concepts out of which all complex meanings and thoughts are built, these concepts must be the same for all people and therefore

Table 1 Table of universal human concepts – English version (cf. Goddard and Wierzbicka eds., 2002)

Substantives	I, YOU, SOMEONE (PERSON), SOMETHING (THING) PEOPLE, BODY
Determiners	THIS, THE SAME, OTHER
Quantifiers	ONE, TWO, SOME, MANY/MUCH, ALL
Attributes	GOOD, BAD, BIG, SMALL
Mental predicates	THINK, KNOW, WANT, FEEL, SEE, HEAR
Speech	SAY, WORDS, TRUE
Actions, events, movement	DO, HAPPEN, MOVE
Existence and possession	THERE IS, HAVE
Life and death	LIVE, DIE
Logical concepts	NOT, MAYBE, CAN, BECAUSE, IF
Time	WHEN (TIME), NOW, AFTER, BEFORE, A LONG TIME A SHORT TIME, FOR SOME TIME, MOMENT
Space	WHERE (PLACE), HERE, ABOVE, BELOW, FAR, NEAR, SIDE, INSIDE, TOUCHING (CONTACT)
Intensifier, augmentor	VERY, MORE
Taxonomy, partonomy	KIND OF, PART OF
Similarity	LIKE (HOW, AS)

*Exponents of primes may be words, bound morphemes, or phrasemes. They can be formally, i.e., morphologically, complex. They can have different morphosyntactic properties (including word class) in different languages. They can have combinatorial variants (allolexes). Each semantic prime has a well-specified set of grammatical (combinatorial) properties.

can be found in the shared lexical repertoire of all languages.

The results of these investigations were first published in *Semantic and lexical universals: theory and empirical findings* (Goddard and Wierzbicka, eds., 1994), then in Wierzbicka's *Semantics: primes and universals* (1996), and finally in *Meaning and universal grammar: theory and empirical findings* (Goddard and Wierzbicka, eds., 2002). The outcome of the search for semantic primitives lexically embedded in all languages has identified 60 odd such elements, listed in Table 1.

From the start, the set of semantic primitives postulated within the 'reductive paraphrase' approach was conceived of as a kind of minilanguage, carved out of natural language (any natural language): it was assumed that although each language varies greatly from all the others in its structure, as well as its lexicon, the lexical and grammatical core of each language is isomorphic to those of all the others. The medieval metaphor of a mental language, *lingua mentalis*, underlying all the 'vocal' languages of the world (*linguae vocales*), was seen as an apt way of talking, and thinking, about the shared core of all languages. At the same time, this shared core was seen as a 'natural semantic metalanguage' (NSM) for description and comparison of meanings.

Two other well-known approaches to semantic primitives are that of the American linguist Ray Jackendoff and that of the Moscow school of semantics. Jackendoff (1983) proposed as innate elementary concept categories like Thing, Event, State, Action, Place, Path, Property and Amount, as well as 'conceptual functions' like GO, STAY, TO, FROM and CAUSE. On the basis of such elements, he sought to develop an abstract semantic metalanguage, relying on artificial devices such as square brackets, pluses and minuses, and so on. In this approach, the focus is not on explanations (that ordinary people would understand) but on technical 'semantic representations.'

The Moscow school of semantics launched their program of semantic analysis based on semantic primitives in a number of pioneering articles by A. K. Zholkovsky (see in particular Zholkovsky 1964). From the start, the Moscow school has insisted on the need for a special 'semantic language' (metalanguage) as a tool for semantic analysis of natural languages. This metalanguage needed a minivocabulary, i.e., a set of semantic primitives, and a minisyntax, i.e., a set of rules for combining those primitives. In the 1960s and 1970s, it was assumed that the semantic primitives can be linked with artificial words, partly borrowed from mathematics or others sciences, and the syntax was a totally artificial construct, relying on devices like semantic graphs and dependency trees.

Over the years, however, the Moscow school has moved away from artificial terms and syntactic devices and has moved closer to the NSM position that the 'semantic language' needs to be a subset of natural language, intelligible via ordinary language. In contrast to several other semantic schools, the work of the Moscow school has resulted in an impressive body of semantic description and, especially, in a series of practically useful, very comprehensive lexicographic works (cf. in particular Apresjan, 1997, 2000a, 2000b, 2003).

Unlike in the NSM approach, in the work of the Moscow school lexicographic definitions and other

semantic descriptions rely largely on 'intermediate concepts' rather than directly on semantic primitives, and in fact no finite set of semantic primitives has yet been proposed. The highly restricted set of primes proposed by the NSM school and used by its practitioners as a tool of description is a major difference between these two schools. At the same time, the key idea of a 'semantic language' carved out of the natural languages and based on intelligible semantic primitives is shared. Furthermore, the increased recent reliance of the NSM school on the use of 'semantic molecules' (as well as semantic primitives) in semantic description is in some ways analogous to the reliance of the Moscow school on intermediate concepts. Overall there is a degree of convergence between the two schools that are the two staunchest defendants of the idea of semantic primitives and that have both sought to show the fruitfulness of this idea through descriptive work with socially useful applications (especially in lexicography but also in other areas).

A total theory of linguistic understanding is often taken to require three subtheories: a syntactic theory, a semantic theory, and a pragmatic theory. The semantic theory occupies an intermediary role – it takes as input structures generated by the syntax, assigns to those structures meanings, and then passes those meanings on to the pragmatics, which characterizes the conversational impact of those meanings. Semantic theories thus seek to explain phenomena such as truth conditions of and inferential relations among sentences/utterances, anaphoric relations among terms, and ambiguity and incoherence of expressions.

One way in which a semantic theory can provide the required explanations is by associating each expression provided by the syntax with a particular entity called its semantic value. These semantic values then serve both to ground the desired semantic explanations and to provide the pragmatic theory with input material on which to operate. While almost any approach to semantic theorizing can be reified into a theory of semantic value – a Davidsonian truth-theoretic account, for example, can associate atomic expressions with axioms and complex expressions with derivations; a translational theory can associate

semantic descriptions rely largely on 'intermediate concepts' rather than directly on semantic primitives, and in fact no finite set of semantic primitives has yet been proposed. The highly restricted set of primes proposed by the NSM school and used by its practitioners as a tool of description is a major difference between these two schools. Semantic Value

J Dever, University of Texas, Austin, TX, USA

© 2006 Elsevier Ltd. All rights reserved.

A total theory of linguistic understanding is often taken to require three subtheories: a syntactic theory, a semantic theory, and a pragmatic theory. The semantic theory occupies an intermediary role – it takes as input structures generated by the syntax, assigns to those structures meanings, and then passes those meanings on to the pragmatics, which characterizes the conversational impact of those meanings. Semantic theories thus seek to explain phenomena such as truth conditions of and inferential relations among sentences/utterances, anaphoric relations among terms, and ambiguity and incoherence of expressions.

One way in which a semantic theory can provide the required explanations is by associating each expression provided by the syntax with a particular entity called its semantic value. These semantic values then serve both to ground the desired semantic explanations and to provide the pragmatic theory with input material on which to operate. While almost any approach to semantic theorizing can be reified into a theory of semantic value – a Davidsonian truth-theoretic account, for example, can associate atomic expressions with axioms and complex expressions with derivations; a translational theory can associate

expressions with expressions in the target language of translation – setting semantic theory in the context of semantic value is most typical of an approach to semantics running through Frege, Carnap, and Montague. This discussion begins with the relatively simple theory of semantic values found in Frege, and progresses through various complications of that basic formula. First, the Fregean framework is extended to a full semantic type hierarchy. Second, the Fregean use of truth as the foundational semantic value is expanded to a notion of indexed truth as the foundational semantic value is expanded to a notion of indexed truth suitable for intensional and context-sensitive languages. Finally, dynamic semantic theories are considered, which diverge from traditional semantic theories by using qualities other than truth to construct semantic values.

Writing in 1891, Frege in 'Function and concept' considers the function $x^2 = 1$ formed by abstracting from an expression such as $(-1)^2 = 1$. Observing that the result of replacing x by various arguments is sometimes a true equation and sometimes a false equation, he says:

> I now say: 'the value of our function is a truth-value [*Wahrheitswert*],' and distinguish between the truth-values of what is true and what is false. I call the first, for short, the True; and the second, the False (Frege, 1997: 137).

Frege's shift from the adjectives 'true' and 'false' to the neologistic nominals 'the True' and 'the False' marks the beginning of semantic theorizing grounded in semantic values. '*Wahrheitswert*' then crosses into English as 'truth value' in Russell's commentary on Frege in 1903 in *The principles of mathematics*, and the contemporary 'semantic value' appears to derive from this usage.

Frege's semantic theory associates with each expression in the language a referent (*Bedeutung*). The various referents are then the semantic values of the expressions in the language. Two central theses governing Frege's conception of semantic value can be identified:

1. The two fundamental types of semantic values are truth values and objects (the referents of singular terms). Other semantic values are derived from the fundamental types through the construction of functions. Call this the categorical principle. Frege recognizes the derived categories of (a) first-level n-ary functions from objects and truth values to objects or truth values (paradigmatically, predicates and truth-functional connectives) and (b) second-order n-ary functions from first-order n-ary functions to objects or truth values (paradigmatically, quantifiers and definite descriptors).
2. Semantic values of complex expressions are derived from semantic values of their composite expressions, typically (although not necessarily) via functional application of one semantic value to another. Call this the compositional principle.

A standard semantic theory for quantified first-order logic can be formulated in Fregean terms by assigning to predicates the characteristic functions of their extensions, to connectives functions from truth values to truth values, and to quantifiers functions from predicate-assigned functions to truth values. The resulting theory will, as desired, account for truth conditions of and inferential connections between sentences. Thus, for example, semantic values can be assigned as follows:

- The predicate 'F,' interpreted as *is French*, is assigned the function f from objects to truth values such that $f(x)$ is the True if and only if x is French.
- The connective '$\vee$,' interpreted as *or*, is assigned the function g from pairs of truth value to truth values such that $g(x, y)$ is the True if and only if at least one of x and y is the True. The connective '$\neg$,' interpreted as *not*, is assigned the function h from truth values to truth values such that $h(x)$ is the True if and only if x is the False.
- The quantifier '$\exists$,' interpreted as *something*, is assigned the function j such that $j(x)$ is the True if and only if x is a function from objects to truth values, which does not map every object to the False.

From these semantic values, it can be determined that $\exists xFx$ is true if and only if something is French, and that $\exists x(Fx \vee \neg Fx)$ is a logical truth.

The basic Fregean framework of semantic values coupled with the categorical and compositional principles then generalizes in three significant directions in later semantic work. First, the space of semantic values is extended to a full type hierarchy based on truth values and objects. The roots of this extension can be seen in Tarski's (1933) paper 'The concept of truth in formalized languages,' but the full implementation of the thought in semantic theorizing about natural languages occurs with Montague's 'The proper treatment of quantification in ordinary English' and Lewis's 'Generalized semantics.' Introductory treatments can be found in Heim and Kratzer's *Semantics and generative grammar* and in the Dowty *et al.*'s (1980) *Introduction to Montague semantics*.

In Montagovian semantics, a categorical grammar is linked with a type hierarchy of semantic values. The categorical grammar takes a small collection of primitive syntactic categories. Ajdukiewicz's work introducing categorical grammars in 'Syntactic connexion' uses *N* (name) and *S* (sentence) as the primitive categories. Derived categories are then defined as follows:

- $<\alpha/\beta>$ = the category of expressions combining with a β-category expression to form an α-category expression.

Thus:

- Intransitive verbs can be of category $<S/N>$. 'Snores' can combine with an expression of category *N* ('Socrates') to form an expression of category *S* ('Socrates snores').
- Nouns can also be of category $<S/N>$. 'Linguist' can combine with an expression of category *N* ('Socrates') to form an expression of category *S* ('Socrates is a linguist'). Placement of nouns in $<S/N>$ is somewhat syntactically forced and is influenced by the treatment of nouns as predicates in first-order logic; other versions of categorical grammar contain a third primitive category *T* of nouns.
- Modal operators can be of category $<S/S>$. 'Necessarily' can combine with an expression of category *S* ('Aristotle is fond of dogs') to form an expression of category *S* ('Necessarily, Aristotle is fond of dogs').
- Quantified noun phrases can be of category $<S/<S/N>>$. 'Some linguist' can combine with an expression of category $<S/N>$ ('snores') to form an expression of category *S* ('Some linguist snores').
- Determiners can be of category $<<S/<S/N>>/<S/N>>$. 'Some' can combine with an expression of category $<S/N>$ ('linguist') to form an expression of category $<S/<S/N>>$, which in turn combines with an expression of category $<S/N>$ ('snores') to form an expression of category *S* ('Some linguist snores').

The type hierarchy of semantic values similarly takes a small collection of primitive semantic categories. Following the Fregean tradition (and setting aside issues of intensionality to be raised below), the primitive categories can be *t* (the set of truth values) and *e* (the set of objects). Derived categories are then defined as follows:

$<\tau, \pi>$ = the set of functions from category π to category τ.

If we then associate each syntactic category with a semantic category via a mapping $[\![\cdot]\!]$ such that:

1. $[\![N]\!] = e$
2. $[\![S]\!] = t$
3. $[\![<\alpha/\beta>]\!] = <[\![\alpha]\!]/[\![\beta]\!]>$

we can then obtain a semantic theory in which the semantic value of any complex expression results from the functional application of the semantic value of one of its immediate constituents to the semantic value of the other of its constituents. Both nouns and intransitive verbs, for example, are assigned functions from objects to truth values. Those functions can then be treated as characteristic functions determining predicate extensions.

This broadly Montagovian framework provides a fertile setting for much work in formal semantics. Barwise and Cooper's (1980) work on generalized quantifiers, for example, fits naturally into such an approach. The categorical grammar yields the categories of $<<S/<S/N>>/<S/N>>$ for determiners and of $<S/<S/N>>$ for quantified noun phrases. The type hierarchy of semantic values then assigns values of type $<<t/<t/e>>/<t/e>>$ to determiners and of type $<t/<t/e>>$ to quantified noun phrases. 'All philosophers' for example, is assigned a function from extensions (in the form of characteristic functions from objects to truth values) to truth values. The appropriate function is that which maps to the True sets that have the set of philosophers as a subset, and to the False other sets. The determiner 'all' then receives as semantic value a function from $<t/e>$ values (predicate extensions) to quantified noun phrase values $<t/<t/e>>$. The appropriate function for 'all' is that which maps each set *X* of objects to the function that maps a set *Y* to the True if and only if $X \subseteq Y$. The type hierarchy yields a natural space of all possible quantifiers, allowing the location of semantic universals governing quantifiers in natural language, of the sort Barwise and Cooper set out. Thus, monotone increasing quantifiers, such as 'some linguist' and 'every mathematician,' are assigned functions *f* such that, for any extensions *X* and *Y*, if *f(X)* is the True and $X \subseteq Y$, then *f*(*Y*) is also the True. Monotone increasing quantifiers thus support inferences of the form:

Some linguist owns a red car. Therefore, some linguist owns a car.

in which the predicate of the conclusion is more restrictive than that of the premise. Monotone decreasing quantifiers, on the other hand, are assigned functions *f* such that, for any extensions *X* and *Y*, if *f*(*X*) is the True and $Y \subseteq X$, then *f*(*Y*) is also the True. Monotone decreasing quantifiers such as 'no

archaeologist' and 'few physicists' support inferences of the form:

Few physicists own a red car. Therefore, few physicists own a car.

in which the predicate of the conclusion is less restrictive than that of the premise. Not all quantifiers are monotone in either direction, as examples like 'an even number of chemists' show – Barwise and Cooper thus hypothesize that all simple natural language quantifiers are conjunctions of monotone quantifiers.

Many complications of the simple type hierarchy of Montagovian semantics can now be investigated. Partee and Rooth's 'Generalized conjunction and type ambiguity,' for example, argues that expressions cannot be assigned a single stable semantic category. In the sentence:

John caught and ate a fish

the transitive verbs 'caught' and 'ate' need to be assigned the category $<<t/e>/e>$. If each transitive verb is assigned a function from entities (e) to intransitive verb extensions ($<t/e>$), then their conjunction will be assigned the function that maps any entity x to the intransitive verb that assigns the True to any entity that caught and ate x. This function can then combine with the entity assigned to 'John' to create an appropriate truth value for the whole sentence. However, this category assignment for transitive verbs fails in other examples such as:

John needed and bought a new coat.

The truth value of this sentence does not depend on a function that maps entities x to intransitive verbs assigning the True to entities that needed and bought x, since we do not here require that John needed and bought any one particular entity. Instead, we require that John needed and bought one type of entity. Thus, the transitive verbs 'needed' and 'caught' must be assigned the category $<<t/e>/<t/<t/e>>>$. By assigning to each transitive verb a function from nouns ($<t/e>$) to truth values, their conjunction will then be assigned the function that assigns the True to any object that needed and bought that type of object. Partee and Rooth (2002) thus suggest that the semantic value assigned to an expression can undergo type raising, which moves it from a simpler to a more complex type to fit constructions such as these.

The second generalization of the core Fregean framework is the move to truth at a specification point. The first instance of this is the intensionalization of Frege's extensional logic. The roots of intensionalization can already be seen in Frege's separation of sense and reference in 'On sense and reference,' but the full picture emerges in Carnap's *Meaning and necessity*. Carnap introduces state descriptions – negation-complete sets of atomic sentences equivalent to possible worlds – and defines truth in a state description. He then assigns to every expression both an extension and an intension. Its extension is its semantic value in the Fregean truth value/object-based type hierarchy, and its intension is its semantic value in a parallel hierarchy based on functions from state descriptions to truth values and functions from state descriptions to objects. Given a designation of an extensionally privileged state description (the actual world), the extensional type hierarchy can be subsumed into the intensional. The intensional type hierarchy is connected conceptually to the Fregean type hierarchy via an understanding of truth at a world in terms of truth simpliciter (what would be true, were the world a certain way). This conceptual connection allows the intensional semantics still to address questions of truth conditions and inferential connections.

The basic insight of the intensionalizing move is that a finer-grained semantics can be achieved by replacing truth values simpliciter in the type hierarchy with indexed truth values, in the form of functions from some set of indexes to truth values. The result is a semantic theory equipped for nontruth-functional operators such as modalities. A similar approach can thus accommodate tense by moving to truth at a time (or at a time/world pair). The same insight is employed in adapting the Fregean framework to context-sensitive expressions. Kaplan, in 'Demonstratives,' gives a semantic theory in which expressions are assigned intensions (both modal and temporal) with respect to a context, where a context provides information at least about utterance speaker, spatial and temporal location, and world. Kaplan's system thus uses a form of double-indexing; the background type hierarchy is grounded on functions from pairs of indices <<world, time>, context> to truth values and objects. Thus, the sentence:

I am a philosopher

can be assigned a truth value only relative first to a context that determines the referent of the indexical 'I' and second to a world–time pair that determines the properties of the contextually provided referent. Kamp's approach to tense in 'Formal properties of now' uses a similar system of double indexing, and Stalnaker (1978) in 'Assertion' gives a streamlined version of the double-indexing

approach, based on Segerberg's (1973) two-dimensional modal semantics, in which both indices are simply worlds.

Context-sensitive semantic theories thus extend the Fregean framework further in the direction begun by intensional semantics, by extending the indexing of truth at the foundation of the type hierarchy. The introduction of double-indexing gives rise to a novel issue in interpretation. The single-indexing of intensional semantics typically comes with a collection, in the analyzed language, of intentional operators that act on the indexing position; thus the expression 'necessarily' binds the world index in the semantic value of expressions it governs, causing them to be evaluated at every possible world. As a consequence, the new foundational semantic category of truth-at-an-index can be reductively understood via the simple truth of some claim containing an intensional operator. For example, a claim ϕ's being true at a world w can be reduced to the intensionally modified claim 'If it were the case that w^*, it would be the case that ϕ's being simply true' (where w^* is a canonical description of world w). However, in double-indexed semantic theories, the second indexed position is typically not subject to semantic interaction with intensional operators of the language. In a sentence such as:

I am always here.

the intensional operator 'always' controls the first index, governing the temporal evaluation of the verb. It does not, however, govern the second index, determining the contextual assignment of semantic values to 'I' and 'here.' Double-indexing thus means that truth at an index can no longer be understood in terms of what would be (or was, or will be) a true simpliciter. It requires instead a novel understanding of the elements of the type hierarchy. The result is the idea that semantic value characterized at a certain level ('utterance meaning') varies based on context of use, so that the same expression can have different semantic contents in different contexts of use.

The third and final generalization of the Fregean framework is the move to dynamic semantics. Dynamic semantics can be thought of as the other side of the coin of context sensitivity, investigating the way that expressions affect, as well as are affected by, context. Dynamic semantic theories have flourished over the last 25 years, taking such forms as discourse representation theory, file change semantics, dynamic predicate logic, and update semantics. When placed in a compositional form, one distinctive characteristic of dynamic semantic theories is a move away from indexed truth to a nontruth-based fundamental semantic value. Overviews of major topics in dynamic semantics can be found in Gamut's (1991) *Logic, language, and meaning* and in Kamp and Reyle's (1993) *From discourse to logic*.

Groenindijk and Stokhof's (1991) dynamic predicate logic, for example, makes dynamic the semantic analysis of sentences of first-order logic using sets of satisfying assignments to variables (where truth is equated with satisfaction by all assignments). In dynamic logic, a sentence is associated not with a static set of assignments, but with a function from input assignments to output assignments. An existential claim of the form '$\exists xFx$' pairs an incoming assignment g with an outgoing assignment h if and only if h satisfies Fx and there is some assignment $g \in G$ such that g and h differ at most in the x position. Quantifiers thus have unrestricted rightward scope; by passing on assignments whose x positions satisfy the existentially quantified matrix, future reference to and description of these objects is then possible. This unrestricted rightward scope allows dynamic predicate logic to model the behavior of crossclausal anaphora on indefinite noun phrases, as in:

A man walked in the park. He wore a hat.

The dynamic move to nontruth-based semantic values is more radical than the intensionalizing move to semantic values based on truth at an index. One consequence is that associated semantic concepts require redefinition. Equivalence, for example, can no longer be understood as sameness of truth value in all models, in the absence of truth-based semantic values. Dynamic predicate logic allows multiple notions of equivalence, the stronger of which is identity of behavior in input–output conditions:

$\phi \simeq \psi$ if ϕ pairs an input assignment g with an output assignment h if and only if ψ does as well.

$\exists xFx \wedge Gx$ is not equivalent to $Gx \wedge \exists xFx$ in this sense, since an assignment g whose x position does not satisfy Gx will produce no output when input to $Gx \wedge \exists Fx$, but can produce an output when input to $\exists xFx \wedge Gx$, since in the latter case the x value can be 'reset' to an object satisfying F and G, if there is such an object. Similarly, dynamic predicate introduces a new consequence relation:

$\phi \models \psi$ if and only if for any model $\mathcal{M}$ and any assignment g in $\mathcal{M}$, if the input of g to ϕ produces some output assignment h, then the input of h to ψ produces some further output assignment k.

The resulting consequence relation differs from classical consequence relations in many structural features. Idempotence fails; we do not have $Gx \wedge \exists Fx \models Gx \wedge \exists xFx$, since the output assignment, with its reset value in the x position, need not satisfy Gx. Transitivity similarly fails, since $\neg\neg\exists xFx \models \exists Fx$ and $\exists xFx \models Fx$, but $\neg\neg\exists xFx \not\models Fx$, since negation blocks dynamic effects.

Semantics in Categorial Grammar

M Steedman, University of Edinburgh, Edinburgh, UK

Introduction

Categorial Grammar (CG) has always held a strong attraction for semanticists, because of the close relationship that it exhibits between syntactic and semantic types, both of which it characterizes as either *functions* or *arguments*. For example, if the semantic type of entities is e and that of propositions is t, then the semantic type $(t \leftarrow e) \leftarrow e$ of the translation *loved′* of the English transitive verb 'loved' as a function from (object) entities of type e to functions from (subject) entities of type e to propositions of type t is reflected in one standard notation in the following syntactic type:

(1) $(S\backslash NP)/NP$

This is the 'result leftmost' notation used in Combinatory Categorial Grammar (CCG), in which the result α of a function category α/β or $\alpha\backslash\beta$ is always to the left of the argument β, and the rightward- or leftward-leaning lashes respectively indicate whether β is to be found to the right or to the left f α/β or $\alpha\backslash\beta$. (We suppress any mention of Categorial Slash Types, which further constrain the syntactic combinatory potential of function categories, and are discussed under **Combinatory Categorial Grammar**). There are several other notations for syntactic categories, including a widely used 'result on top' notation due to Lambek, according to which the preceding category would be written $(np\backslash s)/np$. However, when thinking about semantics it is helpful to be able to read the result/argument distinction via consistent inearization, independent of string order, as in semantic types themselves such as $(t\leftarrow e)\leftarrow e$, pronouncing the semantic type as 't-given-e, given e' (or 'e to e-to-t'), and the syntactic type in (1) as 'S given left NP, given right NP' (or 'right NP into left-NP-into-S').

It is then possible to write the combined syntactic type and translation of 'loved' as in (4), where *loved′* is a function of that type:

(2) $(S\backslash NP)/NP : loved'$

Again, there are other notations, notably the one in which the translation precedes the syntactic category to the left of the colon. However, because the syntactic combinatorics determines semantic composition, the present notation is helpfully consistent with English orthography. The standard forward and backward functional application rules of categorial grammar in (3) then allow us to write syntactic and semantic derivations in parallel, as in

(3) *The functional application rules*
(a) $X/Y : f \;\; Y : a \Rightarrow X : fa \; (>)$
(b) $Y : a \;\; X\backslash Y : f \Rightarrow X : fa \; (<)$

(4)
$$\dfrac{\dfrac{\dfrac{\text{Frankie}}{NP : frankie'} \quad \dfrac{\dfrac{\text{loved}}{(S\backslash NP)/NP : loved'} \quad \dfrac{\text{Johnnie}}{NP : johnnie'}}{S\backslash NP : loved'johnnie'}\,>}{S : loved'johnnie'frankie'}\,<}{}$$

Concatenation $\alpha\beta$ denotes application of α to β, and is 'left associative', so that the preceding translation is equivalent to $(loved'\ johnnie')\ frankie'$.

This approach is readily extended to intensional logic, according to which the type of *loved* might be given as $((t \leftarrow s) \leftarrow e) \leftarrow e$, and the type of the preceding translation is $t \leftarrow s$, a function from situations or possible worlds to truth, rather than simply t.

Because the application rules (3) are completely general and make no reference to any specifics of the logical forms that they combine, semantic translation in such grammars is completely type driven, in the sense of Klein and Sag, so that the derivation in (4) is completely transparent to the logical form. In fact, the one is a homomorphism of the other, so that we can if we like define a model-theoretic semantics directly on the syntactic categories and derivations of English, just as we define the semantics of first-order predicate calculus. Except for the fact that such logical forms eliminate the abundant ambiguity of natural languages, the logical form itself is redundant.

There is a sacred and a profane form of type-driven translation for natural language (the two are distinguished, though not in these terms, by Dowty). The sacred version says that because logical form is redundant in this sense, we should limit its role to that of providing a disambiguated syntactic form. We should define the model theory directly on the (disambiguated) words and syntactic derivations of English itself. Any deviation from strict homomorphism in the logical form is frowned on, although logical forms may be tolerated as a mere notational convenience and concession to the reader's mortal limitations.

The profane version of type-driven translation argues that, because we are lexicalizing the grammar anyway, we may as well allow arbitrary logical forms expressing such clause-bounded grammatical relations as binding and control to be associated with lexical items such as verbs. (Such relations, must under the sacred approach, be captured by syntactic WRAP rules and/or meaning postulates of a kind discussed later.)

Such profane type-driven grammars deliver logical forms that are no longer homomorphic to disambiguated derivations, so that the model theory must be defined over the former, rather than the latter. However, provided such logical forms and the operations that combine them are themselves purely type driven (and in particular do not change the logical forms that they combine with in any way) we can be sure that a sacred version of the grammar could be produced if necessary.

Montague Semantics

The most prominent advocate of the sacred viewpoint was Montague, who pioneered the model-theoretic view that "there is ... no important theoretical difference between natural languages and the artificial languages of logicians," and insisted that the use of logical forms be nonessential.

The details of Montague's own semantic proposal (and the important categorial alternatives by Lewis, and by Keenan and Faltz) are presented elsewhere and need not concern us here (*see* **Montague Semantics**). Although Montague's basic types are defined as categories in the sense of CG, the semantics is otherwise entirely unlexicalized and does not exploit categorial grammar in any significant way. That is to say that it is embedded in a large number of explicit (albeit claimed to be nonessential in the preceding sense – cf. 1973/1974: 256) translation rules and meaning postulates for combining and relating specific words and categories, rather than being associated with specific lexical items combined by general rules like (3). For example, rather than making the translation *seek′* of the intensional verb 'seek' differ from that of 'find,' *find′*, by making the lexical translation of the former but not the latter deliver an intensional reading, both verbs have the higher type required for 'seek.' There is then a meaning postulate for *find′* (but not for *seek′*) that equates the intensional reading with the nonintensional reading (1973/1974: 263,(4)). (That is, it says you find an intensional unicorn (say) if and only if you find an extensional one.)

It is worth pausing to consider this use of meaning postulates, because it raises some issues that will recur. Meaning postulates were introduced by Carnap (for somewhat unrelated reasons), to capture relationships among the nonlogical constants of languages, such as the following relating the property *bachelor′* and the properties *male′* and *unmarried′*:

(5) $\forall x[bachelor'x \Leftrightarrow (male'x \wedge \neg married'x)]$

Such meaning postulates are *axioms*, which is to say that there are no admissible models in which the individuals with the property on the left-hand side of the biconditional do not also have the property on the right, and vice versa, that the meaning of the one is entirely defined by that of the other. (Whether this is a true fact about the corresponding terms in English, and whether such meaning postulates capture linguistic facts or facts of world-knowledge, need not concern us here.) Montague's meaning postulate 1973/4: 264(9) relating *seek′* and *try-to′-find′* is of this apparently harmless kind.

However, a meaning postulate stating an equivalence between an entirely unavailable intensional meaning for *find′* and the standard extensional reading seems rather different. It does not seem like an axiom at all, but rather to be a consequence of the meaning of *finding*. More seriously, rather than relating nonlogical constants or lexical items of the language, it relates entire logical forms. In fact it seems to be an example of the dangerous expressive power of meaning postulates, and the way they can be abused to perform arbitrary side computations to fix up what would otherwise appear to be holes in the theory. Such meaning postulates seem profane in a new and more serious sense, amounting to operations on logical forms.

A number of complications ensue, not least for the category assigned to transitive verbs and the theory of Generalized Quantifiers, which latter is perhaps the most important contribution of Montague's work to natural language semantics. There has been a general tendency in subsequent work in semantics using categorial grammar to make the lexicon and purely categorial syntactic combinatorics do more of the work, even among those of a predominantly sacred persuasion, such as Cresswell, Dowty, Partee, Rooth, Moortgat, Morrill, Hepple, Jacobson, and Carpenter. We will discuss these and other more profane developments by focusing on three specific arenas; lexical semantics, or those relations associated with a specific head and bounded by its local domain; quantifier scope, which is not in general bounded; and pronominal binding, which is both bounded and unbounded.

Lexical Semantics

There are two main ways in which neo-Montagovian semantics has diverged from the original. The first is a general abandonment of the assumption that all categories (noun phrase, transitive verb, etc.) should have the highest type that is needed for any of their members, notably because of Partee and Rooth's 1983 demonstration that any such assumption concerning noun phrases interacts wrongly with the grammar of coordination. The second is the association of much more specific information with lexical items. There

are two ways to do the latter. One is to retain the Montagovian assumption that *find′*, *seek′*, *want′*, and the like are basic types, and to put the specific information into Carnap-Montagovian Meaning Postulates or lexical entailment rules. For example, Chierchia, Dowty, and Jacobson (1992b: 272) treat the control relation for 'equi-NP-deleting' verbs like 'want' in sentences like *John wants to leave* as a relation between individuals and properties, such that for any individual x who stands in the *want′* relation to a property p, px holds in the 'want world' of x – roughly, the possible world that x desires as a function of the world they do the wanting in. Thus we have something like the following, where *want′* is of type $((t \leftarrow s) \leftarrow e)\ (t \leftarrow e)$:

(6a) wants := $(S\backslash NP)/VP : want'$
(6b) $\mathrm{MP}_{want'} = \forall x \forall p \forall s[want' pxs \Leftrightarrow px(wantworld' xs)]$

Alternatively, one can achieve the same effect directly in a lexical entry like the following (in which the symbol *want″* denotes a predicate of a subtly different type $((t \leftarrow s) \leftarrow e) \leftarrow t$ from that of *want′* in (6), cf. Bach):

(7) wants := $((S\backslash NP)/VP : \lambda p \lambda x \lambda s{:}want''(px(wantworld' xs))xs$

This may look dangerously profane, because it includes a logical form, glossed earlier, that does significant work, such as making the subject x of the property p the same as the surface subject of *want′* and makes the language of logical form and English nonhomomorphic. (In particular, *want′* is not a constant of the logical language at all.) However, the profanity in question is venial, because we can always translate lexical entries like (7) into lexical entries like (6a) by making the interpretation $\lambda p \lambda x \lambda s{:}want''(px(wantworld' xs))xs$ of the former into the definition of the interpretation *want′* of the latter in the model theory (cf. Carpenter 1997: 438):

(8a) wants := $(S\backslash NP)/VP : want'$
(8b) $want' \stackrel{def}{=} \lambda p \lambda x \lambda s{:}want''\ (px(wantworld' xs))xs$

In one sense, this amounts to transferring the work of a meaning postulate to the process of interpretation. However, doing it that way seems more wholesome, because it cannot tempt us into the more serious profanity of defining relations over arbitrary logical forms. In which case, doing so directly in lexical logical forms like (7), as Dowty (1979: 199), Calder, Klein, Zeevat, and many computational linguists do, is more helpful, because it puts the same information into one definition, rather than two. We will use this notation from now on, regardless of the version used by the original authors.

Operations over terms that are strictly type driven are what Curry and Feys called 'combinators,' from which the eponymous variety of categorial grammar takes its name. Quite small collections of combinators were shown by Curry and Feys to yield variable-free calculi of the same expressive power as the simply typed λ-calculus. For this reason, some researchers, notably Shaumyan and Szabolcsi, have expressed their semantics directly in a variable-free combinatory calculus, rather than in λ calculus. (We will see examples in a later section on binding). As the two calculi are provably of exactly the same expressive power, and this use of combinators to define lexical semantics is logically independent of the use of syntactic combinatory rules, the difference is merely one of notational convenience, and we will not dwell on it here.

Quantifiers and Scope

Montague's 1973/1974 foundational analysis of quantification was based on a blatantly profane transformational rule schema relating logical forms including indexed pronouns such as $ran' he'_n$ to quantified sentences obtained by λ-abstracting over the pronoun and applying a Generalized Quantifier such as *every′*, as in *every′* $(\lambda x{:}ran' x)$, the translation of 'Everyone ran.' The ambiguity of sentences including multiple quantifiers such as (9) and (10) was accounted for by the possibility of deriving multiple logical forms from a logical form including correspondingly multiple pronouns via freely ordered multiple quantifyings-in.

(9) Everyone loves someone. ($\forall\exists/\exists\forall$)

(10) Someone loves everyone. ($\forall\exists/\exists\forall$)

In a series of publications from 1975 culminating in 1983, Cooper sought to eliminate this syntactic operation from an otherwise Montagovian semantics by treating meanings as pairs $\Lambda;Q$ in which a lambda term Λ (possibly including free variables) was paired with a (possibly empty) quantifier 'store,' Q. Montague-style syntactic rules caused expressions with the type of a generalized quantifier to introduce a (free, distinguished) variable directly into the logical form and to simultaneously introduce a pair consisting of the same variable and the relevant generalized quantifier to the store. At any point in the derivation, such a quantifier–variable pair may be removed from storage, and the quantifier applied to the entire derived expression to bind the variable in question. As in Montague's scheme, different orders of unstoring quantifiers gave rise to different readings for multiply quantified sentences like (9).

Certain general conditions applied to the unstoring process. For example, Cooper (1983: 78) pointed out that there does not seem to be a reading for (11b) in which different people (narrow scope someone) make the claims, in contrast to (11a):

(11a) Someone claimed that Frankie dated everyone. ($\forall\exists/\exists\forall$)
(11b) Someone claimed that everyone dated Frankie. ($^*\forall\exists/\exists\forall$)

Certain 'filters' (notably one that eliminates readings in which variables occur outside the scope of their quantifiers) are also necessary *post hoc* to eliminate overgeneralization. Thus, for examples like the following, one of the six possible orderings of the three quantifiers that would otherwise be permitted by the storage mechanism is eliminated by this filter, namely the one in which *two representatives* outscopes *four samples*, which in turn outscopes *three companies*.

(12) Two representatives of three companies saw four samples.

Cooper storage was later reformulated by Keller and by Shieber, Pereira and Dalrymple in a way that made the bound variable condition emergent. Pereira achieved a related result in a Lambek-style Categorial grammar using a quantifier-abstraction mechanism related to the extraction constructor of Moortgat and Hendriks's early work.

If we lexicalize the Montague account within a categorial grammar, the categories of 'everyone' and 'someone' come out as the following:

(13a) everyone := $S/(S\backslash NP) : \lambda p\colon \forall x[person'x \Rightarrow px]$
(13b) everyone := $(S\backslash NP)\backslash((S\backslash NP)/NP) : \lambda p\lambda y.\ \forall x[person'x \Rightarrow pxy]$
(13c) etc.

(14a) someone := $S = (S\backslash NP) : \lambda p\colon \exists x[person'x \wedge px]$
(14b) someone := $(S\backslash NP)\backslash((S\backslash NP)/NP) : \lambda p\lambda y.\ \exists x[person'x \wedge pxy]$
(14c) etc.

These categories are syntactically and semantically 'type-raised' – that is, they are functions over those functions that take types NP or *e* as arguments and apply those functions to themselves. There is a forward subject category and an object backward category for each. A finite number of further analogous categories will be required for generalized quantifiers as complements of object control verbs, ditransitive verbs, etc. – in fact, all function categories over NP that the grammar allows.

More generally, the determiners 'every' and 'some' translate into the following related generalized quantifier determiner categories:

(15a) every := $(T/(T\backslash NP))/N : \lambda n\lambda p\lambda \ldots .\forall x[nx \Rightarrow px \ldots]$
(15b) every := $(T\backslash(T/NP))/N : \lambda n\lambda p\lambda \ldots .\forall x[nx \Rightarrow px \ldots]$

(16a) some := $(T/(T\backslash NP))/N : \lambda n\lambda p\lambda \ldots .\exists x[nx \wedge px \ldots]$
(16b) some := $(T\backslash(T/NP))/N : \lambda n\lambda p\lambda \ldots .\exists x[nx \wedge px \ldots]$

Here, T schematizes over syntactic types corresponding to the ranges of all functions over NP that the grammar allows, where T may itself be a function type, $\lambda\ldots$ schematizes over λ bindings for the corresponding semantic arguments, if any, and $px\ldots$ schematizes over the application of p to x and those other arguments, if any. There is a forward and a backward syntactic instance for each generalized quantifier. (In English, the former corresponds to a subject and the latter to an object or other complement.)

In a pure (that is, context free) categorial grammar, these categories only allow one of the two readings available for each of (9) and (10). For example, we get the following 'narrow-scope someone' reading for the former, but no 'wide-scope someone' reading:

(17)
$$\dfrac{\dfrac{\text{Everyone}}{\begin{array}{c}S/(S\backslash NP)\\ :\lambda p.\forall y[person'y \Rightarrow py]\end{array}} \quad \dfrac{\begin{array}{c}\text{loves}\\ (S\backslash NP)/NP\\ :loves'\end{array} \quad \begin{array}{c}\text{someone}\\ (S\backslash NP)\backslash((S\backslash NP)/NP)\\ :\lambda p\lambda y.\exists x[person'x \wedge pxy]\end{array}}{S\backslash NP : \lambda y.\exists x[person'x \wedge loves'xy]}\,<}{S : \forall y[person'y \Rightarrow (\exists x[person'x \wedge loves'xy])]}\,>$$

Similarly, we only get the 'wide-scope someone' reading for (10).

We could get around this by modifying the categories along the lines laid down by Cooper, making them store a quantifier-variable pair, allowing a derivation in which the existential in (17) is unstored after the universal, giving it wide scope. However, it is somewhat unclear how to impose the necessary further conditions on unstoring within a lexicalized framework.

Another possibility might be to use Underspecified Scope Representations of the kind first proposed by Kempson and Cormack. However, it is unclear how either storage or underspecification can be made to comply with Geach's 1972 observation that sentences like the following have only two readings, rather than the four that would be expected on a quantifying-in account:

(18) Everyone loves, and everyone hates, someone.

Although there is a reading where everyone both loves and hates the same person that everyone else loves and hates, and a reading where everyone loves someone and hates someone else, there are no mixed readings such as the one where everyone loves

the same person as everyone else but hates someone possibly different from anyone else.

Whether we handle the (unbounded) 'right node raising' extraction of 'someone' by transformational Movement of the surface NP, or by GPSG/HPSG-style 'Slash-passing,' it is hard to see a principled way of excluding the mixed readings on a storage account. It seems as though storage, like quantifying-in, loosens the connection between scoping and syntactic derivational combinatorics too much. Because of this and other over- and undergeneralizations, later work on the semantics of quantifier scope in categorial frameworks has attempted to obtain scope alternations directly from type-driven syntactic combinatorics.

It is therefore interesting that the syntactic apparatus that CCG uses anyway to achieve the equivalent of extraction can be used to give *in situ* object quantifiers scope over the entire sentence. Thus, we can apparently obtain the wide scope reading of (17) as in (20), using the following Forward Composition rule, indexed >**B** in derivations:

(19) *The forward composition rule*
$X/Y : f \Rightarrow Y/Z : g \Rightarrow (\, X/Z : \lambda z.f\,(gz)\ (>\mathbf{B})$

(20)
$$\dfrac{\dfrac{\dfrac{\text{Everyone}}{\begin{array}{c}S/(S\backslash NP)\\ :\lambda p.\forall y[person'y \Rightarrow py]\end{array}} \quad \dfrac{\text{loves}}{\begin{array}{c}(S\backslash NP)/NP\\ :loves'\end{array}} \quad \dfrac{\text{someone}}{\begin{array}{c}S\backslash(S/NP)\\ :\lambda p.\exists x[person'x \wedge px]\end{array}}}{S/NP : \lambda x.\forall y[person'y \Rightarrow loves'xy]}\,{>}\mathbf{B}}{S : \exists x[person'x \wedge (\forall y[person'y \Rightarrow loves'xy])}\,{<}$$

At first glance this looks quite promising, although as an account of scope inversion it will require modification. The same apparatus of type-raising and composition underlies the standard CCG account of *wh*-extraction, on the assumption that wh-elements are functions over *S/NP* and an indirect question has category *Q* and type $t \leftarrow e$ (we ignore the semantics of 'wonder' and the related issue of functional vs. global interpretations of questions):

(21)
$$\dfrac{\dfrac{\begin{array}{c}\text{Frankie}\\ S/(S\backslash NP)\end{array} \quad \begin{array}{c}\text{wondered}\\ (S\backslash NP)/Q\end{array} \quad \dfrac{\begin{array}{c}\text{who}\\ Q/(S/NP)\\ \lambda p\lambda x.person'x \wedge px\end{array} \quad \dfrac{\begin{array}{c}\text{everyone}\\ S/(S\backslash NP)\\ :\lambda p.\forall y[person'y \Rightarrow py]\end{array} \quad \dfrac{\begin{array}{c}\text{loved}\\ (S\backslash NP)/NP\\ :loved'\end{array}}{}}{S/NP : \lambda x.\forall y[person'y \Rightarrow loved'xy]}\,{>}\mathbf{B}}{Q : \lambda x[person'x \wedge (\forall y[person'y \Rightarrow loved'xy])}\,{<}$$

It also allows such extraction to be unbounded, as in (22a), and predicts a number of constraints on extraction, including the Fixed Subject Constraint (22b) and the Across-the-Board Condition on extraction out of coordination (22c):

(22a) I wonder [who]$_{Q/(S/NP)}$ [Johnnie said that Frankie shot]$_{S/NP}$

(22b) I wonder [who]$_{Q/(S/NP)}$ *[Frankie said that shot Johnnie]

(22c) [Frankie loved,]$_{S/N}$P and [I heard that she shot,]$_{S/NP}$ [her man.]$_{S\backslash(S/NP)}$

We therefore predict Rodman's 1976 observation that similar constraints appear to apply to *wh*-extraction and quantifier scoping, as we saw in connection with examples (11) and the 'all wide scope' reading for a right node raised quantifier (as in (18)).

However, there is a difficulty. The grammar as stated does not yet yield the *other* across-the-board Geach reading for (18), the one where 'someone' has narrow scope in both conjuncts. This suggests that derivations like (20) are *not* the way – or at least, not the only way – that existentials gain wide scope.

Following preliminary work in a type-driven categorial framework by van Benthem and by Partee and Rooth, Hendriks (1993, and much earlier work), made a heroic proposal to make scope assignment entirely type driven, using a battery of type-changing rules over and above Montagovian type raising, notably including 'argument lifting' and 'argument lowering.' For example, in order to obtain the narrow scope object reading for sentences (9) and (18), Hendriks, would apparently need to subject the category of the transitive verb(s) to 'argument lifting' to make them functions over a type-raised object type. (The coordination rule must be correspondingly semantically generalized.)

Moortgat (in unpublished technical reports) and Carpenter attempted to lexicalize Hendriks's system using a 'scoping connective,' writing the standard syntactic type-lifted NP generalized quantifier category as $np{\Uparrow}s$, axiomatized within a version of the Lambek calculus, of which Carpenter shows Hendriks's rules to all be theorems. Pereira and Carpenter persuasively suggest that Keller's earlier idea of 'Nested Cooper Storage' is essentially a syntactic reification of the way the categorial grammar makes such properties as the bound variable constraint emerge from the combinatorics of the grammar itself.

However, such schemes are still very expressive. For example, of the remaining five readings for (12), four, according to which the companies either do or do not share the same two representatives, and in which the specific sets of three samples either do or do not vary

with the representatives, are immediately available. However, as Park pointed out, it is much less clear that a fifth reading exists, as claimed by Shieber, Pereira, and Dalrymple, according to which *three companies* outscopes *four samples*, which in turn outscopes *two representatives* – that is, where both representatives of any given company saw the same four samples, but not the same four as the two representatives of either of the other two companies.

There are a number of other constraints that remain hard to explain on any of these accounts. The most striking is the fact that most quantifiers fail to invert scope at all, in the sense of binding a syntactically commanding existential as the true universals *each* and *every* and their derivatives do in sentences like (10). For example, there seems to be no inverting reading for the following:

(23) Some linguist speaks at least three languages. ($\exists \geq 3/\# \geq 3\exists$)

The existentials also appear to differ from the universals in being immune to 'island effects' in their ability to yield wide scope readings, thus

(24a) Every witness claimed that Johnnie had dated some woman. ($\forall\exists/\exists\forall$)

(24b) Every witness claimed that some woman had dated Johnnie. ($\forall\exists/\exists\forall$)

Accordingly, Park, following Fodor and Sag, suggested that the apparent wide-scope readings of existentials in examples like (9) arose from a referential reading for the nonuniversal quantifiers, according to which they referred to a contextually available individual, which gave the appearance of having scope everywhere. When combined with CCG syntax, this immediately explained their inability to invert scope and their indifference to islands, as well as making the across-the-board narrow scope reading for (18) available and explaining the impossibility of mixed scope readings as proposed by Geach under his combinatory categorial approach. Steedman and Farkas proposed ways of obtaining both wide-scope discourse-referential and narrow-scope dependent readings from a single underspecified representation of a referential reading. The former account identifies these representations with a generalization of Skolem terms within a CCG framework and investigates several other ways in which syntax limits available scopings.

The assumption that all quantifiers other than the true universals are (possibly dependent) referential expressions rather than generalized quantifiers also explains their otherwise anomalous ability to apparently bind pronouns that they do not structurally command, as in the famous 'Donkey Sentences':

(25) Every farmer who owns a donkey feeds it.

The preferred reading of the sentence, according to which each farmer feeds the donkey(s) he or she owns, arises not from quantifier binding of *it* by a noncommanding existential generalized quantifier, but by discourse anaphora to a dependent donkey represented by a Skolem term in the variable bound by the universal, which *does* command the pronoun via the category defined at (15a). (This approach to the problem avoids a number of complications that accrue to the standard 'E-type pronoun' and Discourse Representation Theory (DRT) accounts.)

Anaphora

Reflexives

Bach and Partee influentially proposed that reflexive pronouns like 'herself' in sentences like *Frankie cooled herself* had the type of a type-raised NP. In present notation this can be captured in the following lexical entry (26) (we ignore the complication of object-bound reflexives for the moment):

(26) herself := $(S\backslash NP)\backslash((S\backslash NP)/NP) : \lambda v\lambda x{:}self'vx$

Thus, we have:

(27)
$$\dfrac{\dfrac{\text{Frankie}}{\begin{array}{c}S/(S\backslash NP)\\ :\lambda p.p\,frankie'\end{array}} \quad \dfrac{\dfrac{\text{cooled}}{\begin{array}{c}(S\backslash NP)/NP\\ :cool'\end{array}} \quad \dfrac{\text{herself}}{\begin{array}{c}(S\backslash NP)\backslash((S\backslash NP)/NP)\\ :\lambda v.self'v\end{array}}}{S\backslash NP : self'cool'}\,<}{S : self'cool'frankie'}\,>$$

This suggestion (which is also implicit in Geach's account) was taken up by Szabolcsi, Jacobson, Morrill, and Carpenter. In order to prevent the type-raised reflexive category from allowing unbounded reflexive binding analogous to the unbounded quantifer scope inversion in (11a) (contrary to Condition A of the Chomskyan Binding Theory) and in order to enforce nonlocal binding of pronouns (Condition B, discussed later), Bach and Partee added two extra Cooper stores to the grammar, one of which restricted anaphors like reflexives to local binding. Szabolcsi and Jacobson assumed that Condition A followed from other semantic considerations (although not, of course, from profane structural command relations defined over logical forms), but Morrill restricted his version of category (26) to lexical categories using slash modalities, whereas Steedman lexicalized anaphor binding on the verb, obtaining Condition A as a consequence of the intrinsic locality of lexicalization and Condition C (profanely stated).

All of these authors generalized their accounts to cover non-subject-bound local anaphors, and

'pied-piping' of elements like prepositions, as in the following:

(28a) I introduced Frankie and Johnnie to each other.
(28b) *I introduced each other to Frankie and Johnnie.

Pronouns

Bach and Partee treated pronouns like 'her' as type-raised NPs introducing a distinguished variable both into the logical form and into a third 'Superpronoun' Cooper store from which the variable could in due course be unstored to become bound by a (nonlocal) antecedent. This system was used to account for a very wide range of phenomena involving pronouns, including simple intrasentential anaphora, quantifier-bound variable anaphora, 'Donkey Anaphora' of the kind exhibited in (25), and 'Sloppy Anaphora' of the kind exhibited in the following 'Paycheck Sentence', in which 'it' can refer to a different paycheck, as well as the same one:

(29) The woman who put her paycheck in the bank was wiser than the woman who put it in a teapot.

However, adding even one store to a grammar (or the equivalent automaton) can bring about dramatic increases in expressive power, and subsequent accounts again attempted to eliminate storage in favor of more compositional mechanisms.

Szabolcsi treated the pronoun as having a category drawn from a family including the following:

(30a) him := $((S\backslash NP)\backslash(S\backslash NP))\backslash(S/NP) : \lambda f\, \lambda g \lambda x{:}f\,(gx)x$
(30b) he := $((S\backslash NP)\backslash(S\backslash NP))/(S\backslash NP) : \lambda f\, \lambda g \lambda x{:}f\,(gx)x$

This yielded derivations like (31) and (32).

Hepple and Jacobson developed a related account in which the pronoun itself was an identity function, as follows:

(33) him := $NP^{NP} : \lambda x.x$

The superscript ^{NP} is a syntactically inert functional type-constructor, to which none of the standard combinatory rules apply. A 'Geach Rule' G, corresponding to unary application of the composition combinator B, applies to pass ^{NP}-marking up the derivation to a point where a combinatory rule called Z with a semantics identical to that in Szabolcsi's pronominal schema (30) (although in other respects the theories differ) applies to permit the remainder of the derivation to proceed as in Szabolcsi's (31), thus:

In both Szabolcsi's and Jacobson's proposals, a 'family' of Z-rules or Z-related categories (and in the latter case G-rules) is needed to allow for cases like the following, in which multiple binding relations may not be across adjacent elements and may either nest or intercalate – see Jacobson 1999:(23),(29):

(35) Frankie$_i$ said Johnnie $_j$ thinks he$_j$/she$_i$ saw her$_i$/him$_j$.

In this respect, anaphoric relations stand in sharp contrast to standard syntactic multiple dependencies like the following, which generally have to do one or the other:

(36a) Which violin$_i$ is this sonata$_j$ easy to play$_j$ on$_i$?
(36b) *Which sonata$_i$ is this violin$_j$ easy to play$_i$ on$_j$?

Jacobson shows that GZ CCG supports the interpretation of 'Pronouns of Laziness' in 'Paycheck Sentences' like (29) among several other varieties of anaphora.

(31)

Every man	thought	Frankie saw	him
$S/(S\backslash NP)$: $\lambda p.\forall x[man'x \Rightarrow px]$	$(S\backslash NP)/S$: $thought'$	S/NP : $\lambda x.saw'x\,frankie'$	$((S\backslash NP)\backslash(S\backslash NP))\backslash(S/NP)$: $\lambda g\lambda f\lambda x.f(gx)x$

$$\frac{\dfrac{\text{Frankie saw him}}{(S\backslash NP)\backslash(S\backslash NP) : \lambda f\lambda x.f(saw'x\,frankie')x}\,<}{S\backslash NP : \lambda x.thought'(saw'x\,frankie')x}\,<$$

$$\frac{\text{Every man}\quad \text{thought}\quad S\backslash NP : \lambda x.thought'(saw'x\,frankie')x}{S : \forall x[man'x \Rightarrow thought'(saw'x\,frankie')x]}\,>$$

(32)

Every man	thought	he	saw Frankie
$S/(S\backslash NP)$: $\lambda p.\forall x[man'x \Rightarrow px]$	$(S\backslash NP)/S$: $thought'$	$((S\backslash NP)\backslash(S\backslash NP))/(S\backslash NP)$: $\lambda g\lambda f\lambda x.f(gx)x$	$S\backslash NP$: $\lambda y.saw'frankie'y$

$$\frac{\dfrac{\text{he saw Frankie}}{(S\backslash NP)\backslash(S\backslash NP) : \lambda f\lambda x.f(saw'frankie'x)x}\,>}{S\backslash NP : \lambda x.thought'(saw'frankie'x)x}\,<$$

$$\frac{\text{Every man}\quad \text{thought}\quad S\backslash NP : \lambda x.thought'(saw'frankie'x)x}{S : \forall x[man'x \Rightarrow thought'(saw'frankie'x)x]}\,>$$

(34)

Every man	thought	Frankie	saw	him
$S/(S\backslash NP)$	$(S\backslash NP)/S$	$S/(S\backslash NP)$	$(S\backslash NP)/NP$	NP^{NP}
$: \lambda p.\forall x[man'x \Rightarrow px]$	$thought'$	$\lambda p.p\ frankie'$	saw'	$: \lambda x.x$

$$\frac{\dfrac{\dfrac{\dfrac{\dfrac{}{(S\backslash NP)/(S^{NP})}\,{>}\mathbf{Z}}{: \lambda g\lambda x.thought'(gx)x}}{S\backslash NP : \lambda x.thought'(saw'x\ frankie')x}\,{>}}{S : \forall x[man'x \Rightarrow thought'(saw'x\ frankie')x]}\,{>}$$

$$\frac{\dfrac{\dfrac{}{((S\backslash NP)^{NP})/(NP^{NP})}\,{|}\mathbf{G}}{: \lambda q\lambda x.saw'(qx)}}{(S\backslash NP)^{NP} : saw'}\,{>}$$

$$\frac{\dfrac{}{(S^{NP})/((S\backslash NP)^{NP})}\,{|}\mathbf{G}}{: \lambda q\lambda x.qx\ frankie'}$$

$$\frac{}{S^{NP} : \lambda x.saw'x\ frankie'}\,{>}$$

A number of problems remain open for this attractive account of anaphora. One is that it is not yet clear whether the approach can be extended to donkey anaphora of the kind exhibited in (25) (Szabolcsi, 1989: 315; Jacobson, 1999: n. 1). On the assumption from the last section that existentials are referential rather than quantificational, which itself seems to be a forced move in any surface derivational semantics, it seems likely that an extension is possible, because the syntactic position of the donkey is one out of which universal quantifiers can invert scope, and the types seem otherwise compatible with composition via the GZ machinery, in combination with a 'wrapping' combinator – essentially as in Jacobson's analysis of paycheck sentences. The problem of Quantifier Scope in variable-free CCG is discussed by Barker.

A more serious open problem that both Szabolci and Jacobson draw attention to is that neither account of anaphora is compatible with the standard account of syntactic extraction in CCG (see Jacobson, 1999: n. 17). For example, on the earlier standard assumptions about the type of an indirect question, the following derivation in Szabolcsi's version blocks:

(37)

Every man	wondered	what	he	saw
$S/(S\backslash NP)$	$(S\backslash NP)/Q$	$Q/(S/NP)$	$((S\backslash NP)\backslash(S\backslash NP))/(S\backslash NP)$	$(S\backslash NP)/NP$
$: \lambda p.\forall x[man'x \Rightarrow px]$	$wondered'$	$: \lambda q.\lambda y[thing'y \wedge qy]$	$: \lambda g\lambda f\lambda x.f(gx)x$	saw'

$$\frac{\dfrac{((S\backslash NP)\backslash(S\backslash NP))/(S\backslash NP) \quad (S\backslash NP)/NP}{((S\backslash NP)\backslash(S\backslash NP))/NP}\,{>}\mathbf{B}}{: \lambda f\lambda x\lambda y.f(saw'yx)x}$$

The problem is that the type of the category of 'he saw', $((S\backslash NP)\backslash(S\backslash NP))/NP$, is not the same as that of 'Everyone saw,' S/NP in (21). The same is true for the corresponding type S^{NP}/NP in Jacobson's system. As Jacobson pointed out, the GZ mechanism offers no semantically coherent way for the category of 'what,' $Q/(S/NP)$, to shift into something that will combine with S^{NP}/NP.

Jacobson suggested that the CCG account of extraction could be dispensed with and replaced with an autonomous relative clause formation mechanism, such as the feature-passing mechanism of Generalized Phrase Structure Grammar (GPSG). However, to capture the full range of extraction phenomena covered in CCG, including multiple long-range dependencies, is known to be problematic in GPSG. The only constrained way of doing it that is known is equivalent to reimplementing the 'mildly context sensitive' CCG mechanism as a Linear Indexed Grammar via a form of storage. However, the GZ-plus-WRAP apparatus already amounts to an apparatus of at least this power, because CCG is known to be weakly equivalent to a Linear Indexed Grammar, and Geached ^{NP} arguments can stack. It is not immediately clear what combining two such mechanisms in a single grammar would do to its expressive power.

The fact that anaphora is notoriously free from the syntactic constraints that limit relativization, as example (35) shows, makes it seem possible to conclude that Pronoun Anaphora should not be treated in syntax at all. Differences of opinion on this question are not confined to Categorial Grammarians.

Computational Semantics for Categorial Grammars

Although we have used first-order predicate calculus as a semantic representation and the λ-calculus as the

'glue language' for assembling logical forms, as is standard, other representations are possible and may be important in computational applications of Categorial Grammar. Calder, Klein and Zeevat and Bos *et al*. use versions of DRT as a first-order representation language as a basis for inference. Baldridge proposed a 'flatter' Hybrid Logic Dependency Semantics (HLDS), which is better adapted to realization in Language Generation. The properties of such representations are important for computational efficiency, but we will not explore them here.

Conclusion

It appears that the Montagovian vision of a semantically transparent categorial theory of grammar for natural languages is close to realization, with profound implications for our view of both syntax and semantics. The remaining difficulties look soluble and represent the most important challenge for the approach.

Semantics in Psychology

A J Sanford, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Broadly speaking, semantics is the study of meaning – of words and of complete utterances. Formally, semantics is synonymous with logic applied to language, a narrow subset of issues about meaning. Psychological semantics is the application of psychological methods to the study of meaning. In their everyday lives, people use the meaning of words and utterances to convey messages and to understand the messages of others, so inevitably psychological semantics is concerned with, when, and how, meaning is used, as well as with what meaning is from the human perspective.

For convenience, we may divide the psychological study of meaning into several different types. The simplest of these is Lexical Semantics (LS), the study of word meaning. Beyond the word lies the study of utterance meaning. This includes both the meaning of sentences and what the speaker intends to convey, called speaker meaning. Beyond this is discourse semantics, the consideration of meaning beyond single utterances, as in dialog or text discourses.

Content versus Function Words

An important distinction should be made between content and function words. Content (or 'open-class') words include words that convey substance, such as nouns, verbs, and adjectives. Function (or 'closed-class') words include words whose function it is to relate on thing to another, such as prepositions, connectives, and quantifiers. Whereas the closed-class words in a language remain roughly constant, new open-class words may be introduced at any time. Open-class words refer to things (nouns); attributes of things (adjectives); and states, actions and events (verbs). Closed-class words do not refer to anything and effectively tell us how things relate to one another. For instance, in the sentence *John likes Mary because she is fun*, the word *because* tells us that it is being fun that is the reason for John's liking. This distinction means that psychological work is very different for the two classes of word, and we treat them separately in what follows.

Content Words: Features and Decomposition

Following leads in linguistics, much work in psychology has been motivated by the idea that the meanings of words may be represented in terms of (semantic) features. For instance, the word *boy* might be represented as a set of three features:

(1) boy(x) → male(x) & human(x) & not-adult(x)

This amounts to rewriting a word in terms of other words, much as we would find in a dictionary. From a psychological perspective, one idea has been that this information is stored in memory as the meaning of the word and may be made available when the word is read or heard. This simple account has been used to

Semantics in Psychology

A J Sanford, University of Glasgow, Glasgow, UK

© 2006 Elsevier Ltd. All rights reserved.

Broadly speaking, semantics is the study of meaning – of words and of complete utterances. Formally, semantics is synonymous with logic applied to language, a narrow subset of issues about meaning. Psychological semantics is the application of psychological methods to the study of meaning. In their everyday lives, people use the meaning of words and utterances to convey messages and to understand the messages of others, so inevitably psychological semantics is concerned with, when, and how, meaning is used, as well as with what meaning is from the human perspective.

For convenience, we may divide the psychological study of meaning into several different types. The simplest of these is Lexical Semantics (LS), the study of word meaning. Beyond the word lies the study of utterance meaning. This includes both the meaning of sentences and what the speaker intends to convey, called speaker meaning. Beyond this is discourse semantics, the consideration of meaning beyond single utterances, as in dialog or text discourses.

Content versus Function Words

An important distinction should be made between content and function words. Content (or 'open-class') words include words that convey substance, such as nouns, verbs, and adjectives. Function (or 'closed-class') words include words whose function it is to relate on thing to another, such as prepositions, connectives, and quantifiers. Whereas the closed-class words in a language remain roughly constant, new open-class words may be introduced at any time. Open-class words refer to things (nouns); attributes of things (adjectives); and states, actions and events (verbs). Closed-class words do not refer to anything and effectively tell us how things relate to one another. For instance, in the sentence *John likes Mary because she is fun*, the word *because* tells us that it is being fun that is the reason for John's liking. This distinction means that psychological work is very different for the two classes of word, and we treat them separately in what follows.

Content Words: Features and Decomposition

Following leads in linguistics, much work in psychology has been motivated by the idea that the meanings of words may be represented in terms of (semantic) features. For instance, the word *boy* might be represented as a set of three features:

(1) boy(x) → male(x) & human(x) & not-adult(x)

This amounts to rewriting a word in terms of other words, much as we would find in a dictionary. From a psychological perspective, one idea has been that this information is stored in memory as the meaning of the word and may be made available when the word is read or heard. This simple account has been used to

explain a number of empirical phenomena. For instance, it has been widely demonstrated that some members of conceptual classes are better examples of those classes than others. So, although *robin* and *penguin* are both certainly birds, people judge *robin* to be much more typical than *penguin*, and furthermore, if they are asked to make speeded yes/no judgments to questions such as (2), they answer, "yes," more quickly to *robin* than to *penguin*. (The slash denotes optional questions.)

(2) Is a robin/penguin a bird?

The explanation given for this was that, when people evaluate the question, they compare the features of bird (the general concept) with the exemplars, and the overlap in terms of general shape, wing size, ability to fly, and so on gives a greater overlap with *robin*, facilitating the response. This reasoning also explains why, in speeded tasks, people will erroneously affirm that *a whale is a fish*, even though they 'know' that it is not and can recognize their errors. Also, supposed feature overlap between two words has been used to explain the amount of 'priming' one word affords another. In a priming task, participants may be asked to decide whether strings of letters are words or not (lexical decision). The words are presented successively, in pairs, and a decision is made about each one as it is presented. If two words are related to one another (such as *nurse – doctor*), then the second word is judged more quickly than when it follows an unrelated word (as in *bread – doctor*). Feature theories have been used to explain how judgments of the degree to which two words are related in meaning (e.g., *cat* is more similar to *dog* than is *horse*) are made, and figure in many computer implementations of systems that use word meaning.

When the meaning of a word is rewritten as a set of features, as in (1), the question arises as to when the rewriting should stop. For instance, (1) requires that we further rewrite *not-adult* in order to specify **its** meaning. One solution is to seek a set of primitive terms that are not decomposable any further, but this is problematic because every verbal expression is itself is in principle capable of further definition. For linguistic purposes, this may not matter if the idea is to find a small set of words in every language that seem to be fundamental in defining others. But for psychology it is a problem because the idea is to say how people can actually know what a word means. One approach has been to suppose that primitives may be rooted in our nonverbal experiences. For instance, a basic biological activity is to ingest things (such as food and drink). It has been proposed that **ingest** is a primitive for many verbs that involve taking material from the environment into the body (*eat*, *drink*, *suck*, etc.) and that these verbs are just elaborated and specified versions of ingest (see, for instance Schank and Abelson, 1977, for a discussion of primitives including **ingest**; see also Miller and Johnson-Laird, 1976). Rooting meaning outside language itself is discussed in more detail later.

High-Dimensional Space Analysis

In recent years, a new approach to the representation of meaning in abstract terms has enjoyed considerable exploration; in this approach the meaning of a word is treated as a function of the context in which the words occur. One such theory is the Hyperspace Analog to Language (HAL; Burgess and Lund, 1997). The idea is that the meaning of a word can be expressed in terms of its cooccurrence with other words. To determine meaning under these schemes, many occurrences of a word, in context, are found in a corpus. Then a count is made of the number of occurrences of a number of words both preceding and following the word in question (the context words). This gives a distribution in which some context words are frequent and others less frequent. Then, by producing a matrix of the cooccurrence of every word with every other word, a given word's meaning may be characterized and compared to that of any other word; the similarity of two words is the similarity of the vectors characterizing the two words. So, the words that cooccur with *street* in a very large sample of sentences tend to be the same as those that cooccur with *road*. According to high-dimensional space analyses, these words are close in meaning. Expressing words in terms of these vectors does predict some empirical effects. For instance, it predicts the degree to which one word primes another in a lexical decision task: The more similar the words on their metric, the greater the priming. Another high-dimensional approach is latent semantic analysis (LSA; Landauer and Dumais, 1997). In this approach, a large number of contexts is selected (e.g., 30 000+ encyclopedia entries). A matrix is created with 30 000+ contexts as one dimension, each of the words that occurred in these articles is assigned to the other dimension. Then a matrix is constructed showing the frequencies of each word in each of the contexts. The meanings of the words can be compared in terms of values derived from these frequencies, and comparisons between the words can be made. Again, there are correlations between the vector values of words treated in this way and human performance data. For example, using a procedure to express whole sentences in terms of the vectors for the individual words of which they are comprised, it is

possible to predict how coherent successive sentences of a text are rated as being.

Grounded and Embodied Meaning

The problem with all of the approaches considered up to now is that the meanings of words are being expressed in terms of the meanings of other words or in terms of concatenations of other words. Such analyses of meaning run into the symbol-grounding problem (e.g., Harnad, 1990). Harnad discussed a person who lands at an airport in a foreign country, whose language he does not speak. Upon disembarking, he sees a sign he cannot decipher. So, he looks up the first part of the sign in the dictionary of the local language, only to find more indecipherable material. No matter how many of these abstract symbols he looks up and inter-relates, he can never get to meaning of the sign. This is the symbol-grounding problem. Without relating the writing to things in the world, the meaning cannot be determined.

But what does it mean to ground a meaning representation in events in the world? One approach is to link meaning to perception, and another is to link it to the way in which people interact with the world. Such approaches radically move away from simple featural approaches.

Procedural Semantics, Affordances, and Embodiment

An important extension of the feature idea, known as procedural semantics, proposes that the fit of a word to an object, action, or situation can be established by testing for the presence of the features that are supposed to define the word (Miller and Johnson-Laird, 1976). This is particularly useful for objects in the perceptual world, where meaning may be understood in terms of extensions. For instance, we might begin to define *table* as in (3):

(3) table: Is it a physical object?
Does it have a flat surface (of a certain area and shape)?
Does it have a support holding the flat surface off the ground (at the right height and the right angle)?

This example shows one of the problems in trying to produce a list of tests, however. A torchere (a tall candle holder of the eighteenth century), for example, would not normally be called a *table*: torcheres have supports that raise the platform too high for normal use and have a platform that is scarcely large enough to be a normal table. In defining the area and shape of the flat surface and the height and angle of the surface, it is necessary to call on the function of a table. Some surfaces afford certain uses, such as being suitable to write on, eat off, and sit at, and it is this affordance that functionally defines something as a table. This also means that something that is not normally called a *table* (e.g., the stump of a cut-down tree) may be called a *table* if we are looking for a picnic spot. So, sometimes, even describing a thing in terms of its physical attributes cannot easily be done without taking its function into account.

Many kinds of motion words cannot be described properly in terms of other words. For example, consider the walking verbs *shuffle* and *trudge*. Ultimately, the meanings of these must be given by their extensions, that is, by examples of making these movements. It has been shown that the information conveyed by the movements of the joints of a person, in side view, is adequate to enable people to correctly use the appropriate verb to describe the motion. Almost certainly, the meanings of these words consist of stored procedures for recognizing the movements when they occur, not words that may be used to capture some aspects of them.

Evidence from investigations of brain function suggests that the meanings of action words may be stored in the same parts of the brain as the procedures for carrying out the actions. For example, Pulvermüller and his colleagues (see Pulvermüller, 2003, for a review) had participants perform a lexical decision task in which they had to decide whether strings of letters were words. Verbs referring to actions normally performed with different parts of the body were used, for instance, leg-related words, such as *walk*, and face-related verbs, such as *talk*. While performing the task, event-related brain potentials (ERPs) were recorded using 60 electrodes at a wide range of sites on the scalp. They found that differences among ERPs for the words were found on the scalp above the cortical motor strip and adjacent frontal cortex, associated with the production of movements themselves. At the vertex of this strip, there is a cortical representation of leg actions. At this location, there was a strong ingoing current for leg-related verbs, such as *run*, *kick*, and *sprint*. Face-related verbs, such as *talk*, *gnaw*, and *whistle*, gave the strongest ingoing currents near the left Sylvian fissure, where the articulator actions (e.g., of the mouth and tongue) are represented. Similar results, comparing arm- and leg-related words have been obtained using functional magnetic resonance imagery (fMRI). Evidence such as this suggests that the representation of verbs of action may be in terms of representations of the motor activities that they depict; in other words, the verbs'

meanings are embodied in action (Pulvermuller, 1999).

The Indexical Hypothesis

These observations have motivated the Indexical Hypothesis as an idea of how meaning is established by humans (Glenberg and Robertson, 1999). The basic idea is that when we understand an utterance, such as *John stood on the chair to change a lightbulb*, we index the phrases to perceptual representations of the objects they denote. We then use the representation to derive affordances (for instance, a chair will afford being able to stand on it to reach something). Finally, the affordances of all the things mentioned are meshed together to form a final representation. Regardless of the details of this idea, the point is that not only are perceptual representations used, they are used to determine what is being depicted from what is possible based on what those entities afford.

Such an approach has the merit of suggesting a solution to some knotty problems of the novel uses of words. Novel uses provide a major challenge for theories of meaning based on abstractions (such as simple feature theories and high-dimensional analyses). One example is denominal verbs. These are nouns that are treated as verbs, such as *John* ***motored*** *to Scotland,* and novel uses are easily made, for instance, *this Christmas, Mary* ***parceled*** *her way to popularity with the kids*. Here, *parceled* can be used because a Christmas parcel affords popularity if it is given. But this is completely different from *Mary parceled the books and sent them to her sister in Alaska*. Experiments show that people easily understand such uses, rating them as sensible and easy to envision, even though they do not fit well with LS analyses (see Glenberg and Robertson, 2000, for a technical discussion).

Combining Words: Compositionality and Blending

The traditional view of how word meanings are combined is that the underlying semantics is compositional. The meaning of a sentence, for example, is the sum of the meanings of the words making up that sentence. This idea is quite compatible with the feature account of meaning, but it runs into difficulties when confronted with a number of commonplace phenomena. One of these is nominal compounds, as in *John died from a* ***knife wound***. Clearly the meaning of *knife wound* cannot be derived from the separate dictionary meanings of *knife* and *wound*. In processing terms, what is required to understand this construction is the invocation of situation-specific knowledge combining ideas about dying from a wound inflicted by a knife. The semantics thus depends on background knowledge of situations and cannot be derived from the 'meanings' of words in the sentence, any more than can the example of denominal verbs discussed previously (see Coulson, 2001, for a discussion of these issues and many others that challenge the compositional view). One simple psychological study (see Rips, 1995, for an overview) took concepts such as *smoky chimney* and *smoky apple* and asked people to list their properties and also to list the properties of the individual components (*apple, smoky*, etc.). For the compound, properties were listed that did not appear at all in the individual elements. This shows how a simple compositional account runs into difficulties. When we consider the fuller range of modifiers, the difficulties become even more obvious. For instance, it has been claimed that examples such as *cruelty-free make-up* rely on somewhat peripheral aspects of the words themselves rather than their core meanings and, in fact, depend on the presence (in the mind) of a strong alternative (in which make-up relies on animal testing that may be cruel). Although the trend in psychology is now away from compositional approaches, at a theoretical level it has its defendants (for problems see Franks, 1995; and especially Coulson, 2001).

Function Words

Closed-class, or function, words have to be treated somewhat differently from open-class items. They include a whole range of items, and here two are examined in some detail because they have received much attention from psychologists. Another class of function words are known as cue-phrases, and these serve to indicate how the propositions and utterances in a discourse are to be related to one another. They include connectives such as *when* and *while*, *hence* and *because*, and *so* and *since*. Because their primary function is to connect parts of discourse, the psychological treatment of these items is described elsewhere (*see* **Coherence: Psycholinguistic Approach**) and is not discussed any further here.

Spatial Prepositions

In psychology, because of the ubiquity of descriptions of things in relation to one another in space, among the most extensively studied function words are spatial prepositions. Spatial prepositions occur in all languages, but do not easily translate from one language to another, being among the most difficult terms to master in new language learning. They include *in, on, at, above, below, over,* and *under* – all

mundane, everyday words. Yet defining these words is surprisingly difficult. Consider *in*. The earliest attempts to define *in* were in terms of inclusion of an object within the boundaries of a one-, two-, or three-dimensional object. Thus, if an apple is within the boundaries of a jar, then it is true to say *the apple is in the jar* (three-dimensional enclosure). But there are difficulties with this simple idea. Suppose that there is a pile of fruit in a bowl, with a pear on the very top of the heap, such that it clearly protrudes over the top of the jar. It is still true to say *that the pear is in the bowl*, even though it is true that the pear is outside of the strict three-dimensional confines of the jar. Similarly, we say that *the lightbulb is in the socket*, even though most of the lightbulb is not physically within the three-dimensional confines of the socket. Similar problems occur with simple geometric accounts of all the other spatial prepositions (see Coventry and Garrod, 2004, for a thorough review, and Herskovits, 1986, for geometrically oriented account). One likely solution is that spatial prepositions do not simply express the spatial relations between things; they also express functional relations between things. For instance, it has been suggested that *in* expresses a relation of functional containment, which means that, if A functionally contains B, then B's location controls A's location by virtue of some degree of spatial enclosure. At the extreme, if something is in a box and you move the box, you move the thing, too, because it is functionally contained. So, moving a jar with a pear completely contained moves the pear too; but also moving a socket moves the whole lightbulb and moving a bowl of pears moves a pear that is largely protruding from the bowl. Experiments testing this sort of notion have been carried out using displays in which pears protrude from a bowl and either do or do not move when the bowl is moved. In the former case, *in* is taken as an appropriate description, whereas, in the latter, it is not. In general, with spatial prepositions functionality is most important when the relation depicts less obvious geometrical configurations.

Comparisons of *in, on,* and *at* have proven very enlightening, in that they differ in the amount of control they seem to entail. Thus, if *x is in y*, then x is controlled by y; if *x is on y*, then y supports x; and if *x is at y*, x and y are in close proximity but there is no control relationship (see Coventry and Garrod, 2004). Possible extensions of this approach might be applicable to different ways of describing containment more generally, such as (4), which could imply that wearing the suit is controlling John's behavior:

(4) John is in his suit.

or (5), which could imply that whatever John is doing is supporting wearing a suit:

(5) John has his suit on today.

Spatial prepositions pose a huge problem when it comes to determining which form of description is appropriate, despite their apparent simplicity, and psychological experimentation using people's judgments of when it is appropriate to use particular words offers a clear way forward.

Quantifiers and Expressions of Amount

A second widely occurring set of expressions is quantifying determiners (such as *all, none, most, few,* and *many*) and closely related expressions such as adverbs of frequency (such as *often, rarely, occasionally, regularly,* and *sometimes*), certainty (*certain, unsure,* and *not sure*), and probability (*likely, unlikely, not likely, probable,* and *improbable*). These words occur all the time in daily conversation, weather reports, descriptions of the side-effects of medicine, statements of risk, and so on and are of immense practical significance in addition to posing interesting theoretical problems.

Psychologists have long been interested in specifying the meanings of these terms, and the studies have given rise to a rash of papers with titles like 'How many is many?' Determining the answer to questions like this sounds easy but is virtually impossible. Many studies have been carried out to determine what numbers (percentages, say) might be a (numerical) translation of statements such as *many of the students failed their exam*. Rather than showing that percentages or numbers associated with quantity expressions were stable and consistent, the studies have established that the numbers depend on context. For instance, *many* and *some* mean a larger quantity if a lot is expected to be the case than if little is expected to be the case. So, if we say *many people enjoyed the party*, the mean value assigned might be 70%, whereas, if we say *many of the surgeons at the hospital are female*, the value will be much lower because people's expectations are lower. Expectations are influenced by what a person is used to, so for a person who visits the cinema three times a week *Jamie frequently goes to the cinema* will mean he goes, say, at least twice a week, whereas for a person who goes once a year *frequently* might mean only once a month. Apart from context, it has also been established that there is considerable variability in the assignments people give for judgments in the same context. Moxey and Sanford (1993, 2000), reviewing a wide range of studies, suggested that quantifiers simply do not denote specific

amounts. They suggested that quantity expressions typically convey only vague quantitative information and that they serve other functions, accounting for their variety.

One other function is perspective cueing. Compare (6) with (7).

(6) Few people enjoyed the meeting.

(7) A few people enjoyed the meeting.

Example (6) puts emphasis on the large set of people who did **not** enjoy the meeting, whereas (7) puts emphasis on the few people who did. This difference explains the different conditions under which speakers choose to use (6) and (7). The contrast of *few* and *a few* finds parallels in frequency expressions (*seldom* vs. *occasionally*) and expressions of riskiness (*little risk* vs. *slight risk*). In all these cases, the difference between the expressions is that the cases that parallel *few* are negative, whereas those paralleling *a few* are positive.

Semantics in Processing

Grappling with how humans understand the meanings of things naturally leads to questions of how processing works, a question at the heart of psychology. Two key issues are ambiguity resolution and the processing of metonymies.

Ambiguity and Metonomy

During understanding, the processor has to select appropriate senses of a word. For instance, the word *bank* is polysemous ('river bank' vs. 'savings bank'). Much effort has been spent on trying to determine when context leads to the selection of the appropriate sense of such words. Using priming techniques, it would appear that the appropriate sense is selected very early after the word has been encountered but that the inappropriate meaning is briefly retrieved and then inhibited shortly afterward, unless that sense is a very unlikely use. So, context influences meaning selection at a very early stage.

An interesting limitation occurs in the case of less radical sense differences, as with *newspaper*, in which the senses include the physical product and the organization. Although different, these senses are correlated, unlike the two meanings of *bank*. There is evidence to suggest that even in a context in which it is possible to decide which of the two or more senses of newspaper are intended, readers simply do not determine which one it is. The argument is that it does not matter for comprehension, so the details of the meaning are left underspecified.

Underspecification is an important concept, and it has been suggested that sometimes we may work out the meanings of language only as far as is necessary for the task at hand. Another example of this is found with the treatment of metonymy. For instance, the term *Vietnam* might be used to refer to the country itself (*John went to Vietnam*) or to the war that was fought there (*John protested against Vietnam*). Recent research has shown that people often do not discriminate between these possibilities when there is no need to; hence, there is mental underspecification of the word (see Sanford and Sturt, 2002, for an overview of these and other examples).

Semantic Illusions

Closely related to underspecification in comprehending meaning is a family of effects known as semantic illusions. These show how shallow our processing of word meaning can be. Three examples are:

(8) Suppose there was an aircrash right on the border of Iraq and Iran. Where should the survivors be buried?

(9) Can a man marry his widow's sister?

(10) No head injury is too trivial to ignore.

In example (8), people often miss the fact that we do not bury survivors. In (9), people often answer "yes," even though, if a man has a widow, he is dead and therefore unable to marry. Example (10) is particularly difficult, in that it reads as though the assertion were *no matter how trivial a head injury is, it should be treated*. In fact, it says nothing of the kind.

These examples show how, in practice, people do not make use of the full meanings of words when they read. Sometimes this is because people recognize what the message is supposed to be without working out in detail what the message actually says. In the case of (10), **treating** a head injury, no matter how trivial, is a standard idea, and this is how (10) is interpreted. This shows that getting a full sentence meaning does not necessarily precede interpreting the sentence against background knowledge. Such a finding is compatible with how the meanings of denominal nouns must be established, as discussed earlier. See Sanford and Sturt (2002) for a review.

Semantics plays a central role in Role and Reference Grammar (RRG). The aspects of semantics in RRG that are addressed herein are (1) the lexical representation of verbs and other predicating elements, (2) semantic roles, (3) the role of the lexicon in grammar, and (4) interclausal semantic relations. An overview of the theory as a whole is given in a companion article (*see* **Role and Reference Grammar**).

The Lexical Representation of Verbs

The heart of the RRG approach to lexical representation is a system of lexical decomposition based on Vendler's (1967) *Aktionsart* classification of verbs into states, activities, achievements, and accomplishments. In addition, there is a class of semelfactive verbs (Smith, 1997), and the telic uses of activity verbs are termed active accomplishments. Each of these classes has a causative counterpart, and examples of each class are given in **Table 1**. These classes can be characterized in terms of four features, [± static], [± dynamic], [± telic], and [± punctual], as shown in **Table 2**.

Table 1 Active and causative accomplishments of activity verbs

Class	*Active*	*Causative*
State	The boy is afraid of the snake.	The snake frightens/scares the boy.
Activity	The soldiers marched in the park.	The sergeant marched the soldiers in the park.
Achievement	The soap bubble popped.	The cat popped the soap bubble.
Semelfactive	The light flashed.	The policeman flashed the light.
Accomplishment	The water froze.	The cold froze the water.
Active accomplishment	The soldiers marched to the park.	The sergeant marched the soldiers to the park.

Semantics plays a central role in Role and Reference Grammar (RRG). The aspects of semantics in RRG that are addressed herein are (1) the lexical representation of verbs and other predicating elements, (2) semantic roles, (3) the role of the lexicon in grammar, and (4) interclausal semantic relations. An overview of the theory as a whole is given in a companion article (*see* **Role and Reference Grammar**).

The Lexical Representation of Verbs

The heart of the RRG approach to lexical representation is a system of lexical decomposition based on Vendler's (1967) *Aktionsart* classification of verbs into states, activities, achievements, and accomplishments. In addition, there is a class of semelfactive verbs (Smith, 1997), and the telic uses of activity verbs are termed active accomplishments. Each of these classes has a causative counterpart, and examples of each class are given in Table 1. These classes can be characterized in terms of four features, [± static], [± dynamic], [± telic], and [± punctual], as shown in Table 2.

Table 1 Active and causative accomplishments of activity verbs

Class	*Active*	*Causative*
State	The boy is afraid of the snake.	The snake frightens/scares the boy.
Activity	The soldiers marched in the park.	The sergeant marched the soldiers in the park.
Achievement	The soap bubble popped.	The cat popped the soap bubble.
Semelfactive	The light flashed.	The policeman flashed the light.
Accomplishment	The water froze.	The cold froze the water.
Active accomplishment	The soldiers marched to the park.	The sergeant marched the soldiers to the park.

The most fundamental contrast is between static and nonstatic verbs, which distinguishes verbs that code a 'happening' from those that code a 'non-happening.' The feature [± dynamic] refers to whether the state of affairs involves action or not. The feature [± telic] concerns whether a verb indicates a state of affairs with an inherent temporal boundary or not; this can be either the onset of an action or the end of a process or action leading to a result state. Finally, the feature [± punctual] differentiates events with internal duration from those without. Achievements and semelfactives are both punctual, but they differ with respect to telicity: achievements have a result state or action (hence they are telic), whereas semelfactives do not (hence they are atelic).

These distinctions underlie the syntactic and semantic tests for the six noncausative classes. The tests are given in Table 3 (see Van Valin, 2005, for detailed discussion of the tests and their complications). The causative versions of these classes all pass the causative paraphrase test.

The formal representation of the *Aktionsart* classes is based on, but not identical with, the decompositional system proposed originally in Dowty (1979). The representations for the classes are given in Table 4. INGR or BECOME plus state predicate signals a change of state (see examples of achievements and accomplishments in Table 5), whereas INGR or BECOME plus activity predicate signals an onset of an action, for example, Russian *zaplakat'* 'burst out crying' (INGR **do**′ (x, [**cry**′ (x)])) versus *zagovorit'* 'start talking' (BECOME **do**′ (x, [**talk**′ (x)])). Semelfactives may be based on either an activity predicate, for example,. *flash* (SEML **do**′ (x, [**flash**′ (x)])), or a state predicate, for example, *glimpse* (SEML **see**′ (x, y)). Some work has been done on decomposing state and activity predicates (see Van Valin and Wilkins, 1993; Mairal and Faber, 2002).

The decompositional representation of a predicate is referred to as its 'logical structure' (LS). Examples of English verbs (and also some nonverbal predicates) with their LSs are given in Table 5. The order of arguments is discussed in the next section. Despite having INGR in their LSs, the telic use of activity verbs is, following the literature, referred to as '(active) accomplishments.'

In many languages, verbs in these different classes may be overtly morphologically inflected to signal their class, and verbs in different classes may be morphologically related to one another. State predicates are the basis of change of state verbs, achievements, and accomplishments, and these in turn are the basis for causative change of state verbs, causative achievements, and accomplishments. There are languages that represent these relationships explicitly in their verbal morphology. These languages fall into a number of groups (Haspelmath, 1993), two of which are discussed here. In the first group, the base is a state predicate, either a verb or an adjective, and to this base a morpheme is added that indicates BECOME or INGR, deriving an accomplishment or achievement. Then, to this derived form is added a causative morpheme, deriving a causative accomplishment or achievement. In Northern Qiang, a Tibeto-Burman language (Van Valin and LaPolla, 1997), the relationship is straightforward:

Table 2 Features of classes

Class	*Features*
State	[+ static], [− dynamic], [− telic], [−punctual]
Activity	[− static], [+ dynamic], [− telic], [− punctual]
Achievement	[− static], [− dynamic], [+ telic], [+ punctual]
Semelfactive	[− static], [± dynamic], [− telic], [+ punctual]
Accomplishment	[− static], [− dynamic], [+ telic], [− punctual]
Active accomplishment	[− static], [+ dynamic], [+ telic], [− punctual]

Table 3 Tests for *Aktionsart* classes[a]

Criterion	*State*	*Achievement*	*Semelfactive*	*Accomplishment*	*Activity*	*Active accomplishment*
1. Occurs with progressive	No*	No*	No*	Yes	Yes	Yes
2. Occurs with adverbs like *vigorously, actively*, etc.	No	No	Some*	No	Yes	Yes
3. Occurs with adverbs like *quickly, slowly*, etc.	No	No*	No*	Yes	Yes	Yes
4. Occurs with *X for an hour, spend an hour Xing*	Yes*	No*	Yes*	Irr*	Yes	Irr*
5. Occurs with *X in an hour*	No	No*	No*	Yes	No	Yes
6. Can be used as stative modifier	Yes	Yes	No	Yes	No	Yes
7. Has causative paraphrase	No	No	No	No	No	No

[a] * Indicatives complications arise with this test; Irr, irrelevant.

ba	'big'	[state]
tə-ba	'become big'	[accomplishment]
tə-ba-ʐ	'cause to become big'	[causative accomplishment]

Consider the examples in Table 6, from Huallaga Quechua Huallaga Huánuco Quechua). In Table 6 examples (a)–(d), accomplishment verbs are formed from state predicates by the addition of the suffix *-ya:* 'become' and causative accomplishments are formed from them by the addition of the causative suffix *-chi*. As Table 6 examples (e)–(f) show, *-chi* can be added to underived accomplishment verbs as well.

The second group of languages exhibits a rather different pattern expressing the same relationships; it includes Yagua (Peru), Russian, and French (see Table 7). In these three languages, the base form of the verb is a transitive causative accomplishment, and the intransitive accomplishment and state forms are derived morphologically from it.

The derivational relationships illustrated in Tables 6 and 7 can be readily accounted for in terms of this system of lexical decomposition. The state → accomplishment → causative accomplishment pattern found in Qiang and Huallaga Quechua follows directly from the lexical representations; for example, in Table 6 examples (c), *hatun-* (**big**′ (x)) → *hatun-ya:-* (BECOME **big**′ (x)) → *hatun-ya:-chi-* (. . . CAUSE [BECOME **big**′ (x)]). The pattern in Yagua, French, and Russian also indicates a systematic relationship among these classes, but the function of the morphological markers is to cancel part of the LS rather than to add components to it; for example, in the Yagua examples in Table 7, *-muta-* (. . . CAUSE [BECOME **open**′ (x)]) → *-muta-y-* (BECOME **open**′ (x)), in which *-y-* cancels the '. . . CAUSE' part of the LS, → *-muta-y-maa* (**open**′ (x)), in which *-maa* cancels the 'BECOME' part of the LS. The examination of the verbal systems of a number of languages had led to the conclusion that this set of distinctions is one of the fundamental organizing principles of verbal systems in human language.

The semantic representation of a clause contains information about operators such as illocutionary force and tense in addition to the predicating element's LS. A simple example is given in (1).

(1a) Are the children playing?
(1b) $<_{IF}$ *INT* $<_{TNS}$ *PRES* $<_{ASP}$ *PROG* <[**do**′ (children, [**play**′ (children)])]>>>>

Table 4 Formal representations of *Aktionsart* classes

Class	*Formal representative*
State	**predicate**′ (x) or (x,y)
Activity	**do**′ (x, [**predicate**′ (x) or (x, y)])
Achievement	INGR(ESSIVE) **predicate**′ (x) or (x,y), or INGR **do**′ (x, [**predicate**′ (x) or (x, y)])
Semelfactive	SEML **predicate**′ (x) or (x,y), or SEML **do**′ (x, [**predicate**′ (x) or (x, y)])
Accomplishment	BECOME **predicate**′ (x) or (x,y), or BECOME **do**′ (x, [**predicate**′ (x) or (x, y)])
Active accomplishment	**do**′ (x, [**predicate**$_1$′ (x, (y))]) & INGR **predicate**$_2$′ (z, x) or (y)
Causative	α CAUSE β, where α, β are representations of any type

Table 5 Logical structures of predicates in English

Class	*Example*	*Logical structure*
States	Sam is a lawyer.	**be**′ (Sam, [**lawyer**′])
	The vase is shattered.	**shattered**′ (vase)
	Chris is at the office.	**be-at**′ (office, Chris)
	Kim saw the photo.	**see**′ (Kim, photo)
Activities	The door squeaks.	**do**′ (door, [**squeak**′ (door)])
	Lee drank beer.	**do**′ (Lee, [**drink**′ (Lee, beer)])
Achievements	The vase shattered.	INGR **shattered**′ (vase)
	The bubble popped.	INGR **popped**′ (bubble)
Semelfactives	Lee sneezed.	SEML **do**′ (Lee, [**sneeze**′ (Lee)])
	Chris glimpsed Pat.	SEML **see**′ (Chris, Pat)
Accomplishments	The water froze.	BECOME **frozen**′ (water)
	The sky reddened.	BECOME **red**′ (sky)
	Kim learned Swahili.	BECOME **know**′ (Kim, Swahili)
Active accomplishments	Lee drank a beer.	**do**′ (Lee, [**drank**′ (Lee, beer)]) & INGR **drunk**′ (beer)
	Paul ran to the store.	**do**′ (Paul, [**run**′ (Paul)]) & INGR **be-at**′ (store, Paul)
Causatives	The dog scared the boy.	[**do**′ (dog, Ø)] CAUSE [**feel**′ (boy, [**afraid**′])]
	Mary broke the pencil.	[**do**′ (Mary, Ø)] CAUSE [BECOME **broken**′ (pencil)]
	The cat popped the bubble.	[**do**′ (cat, Ø)] CAUSE [INGR **popped**′ (bubble)]
	Fred rolled the ball.	[**do**′ (Fred, Ø)] CAUSE [**do**′ (ball, [**roll**′ (ball)])]

Table 6 Verbs in Hullaga Quechua

State	*Accomplishment*	*Causative accomplishment*
a. qarwash- yellow 'be yellow'	qarwash-ta:- yellow-become 'become yellow'	qarwash-ta:-chi- yellow-become-cause 'make something yellow'
b. hanq̀a- above.on.slope 'above'	hanq̀a-ya:- above.on.slope-become 'become higher'	hanq̀a-ya:-chi- above.on.slope-become-cause 'make something higher'
c. hatun- big 'be big'	hatun-ya:- big-become 'become bigger'	hatun-ya:-chi- big-become-cause 'make something bigger'
d. umasapa- big.headed 'be big-headed'	umasapa-ya:- big.headed-become 'become big-headed'	umasapa-ya:-chi- big.headed-become-cause 'make someone big-headed'
e. —	wañu- die 'die'	wañu-chi- die-cause 'kill'
f. —	yacha- learn 'learn'	yacha-chi- learn-cause 'teach'

From Weber (1989).

Table 7 Verbs in Yagua, French, and Russian

Language	*Causative accomplishment*	*Accomplishment*	*State*
Yagua[a]	-muta- 'open'	-muta-y- 'open'	-muta-y-maa 'be open'
French	briser 'break'	se briser 'break'	brisé 'broken'
Russian	razbit' 'break'	razbit'sja 'break'	razbityj 'broken'

[a]Data from Payne and Payne (1989).

Semantic Roles

The RRG theory of semantic roles is rather different from that of other theories, in that it posits two types of semantic roles. The first are specific thematic relations, the traditional (since Fillmore, 1968; Gruber, 1965) notions of agent, theme, patient, experiencer, and so on. The second are generalized semantic roles called 'semantic macroroles'; they were introduced in Van Valin (1977) and have no exact analog in other theories, although Jackendoff's 'action tier' and Dowty's proto-roles bear some resemblance (see Van Valin, 1999, for a comparison of the different theories of generalized semantic roles). Following the ideas of Gruber (1965) and Jackendoff (1976), RRG defines thematic relations in terms of argument positions in LSs such as those in Tables 4 and 5. All thematic relations are defined in terms of argument positions in state and activity LSs; all other LS types are composed of them plus elements such as BECOME, INGR, and CAUSE.

The thematic relations posited in RRG are given in Table 8. Well-known relations such as recipient and goal are possessor or location arguments embedded under BECOME/INGR, whereas motion and transfer sources are location and possessor arguments embedded under BECOME/INGR NOT. Instruments are intermediate inanimate effectors in a causal chain. In verbs that lexicalize agency (e.g., *murder*), agent is represented by 'DO (x, . . .', following Dowty (1979). However, in most cases, agent is an implicature related to human effectors with certain types of activity predicates and is not represented in the LS of the verb (see Holisky, 1987; Van Valin and Wilkins, 1996). Because thematic relations have no independent status, they are really just mnemonics for the argument positions in LSs; for example, 'experiencer' stands for 'the first argument of a two-place state predicate of internal experience'.

Table 8 could give the impression that RRG posits a great many thematic relations, but in fact there are only five relevant distinctions. The five distinctions correspond to the five possible argument positions in LSs. This may be represented as in Figure 1. Agents are willful, controlling, instigating participants in states of affairs, whereas patients are strongly affected participants. Positing these as end points on the cline makes it possible to locate the other role types with regard to them. The DO of lexicalized agency always co-occurs with **do**′ (x, . . ., which defines effector and its subtypes, and therefore the first two columns are closely related to one another; both of them expressing participants that do something. At the other end of the continuum are patient, theme, and so forth. The single argument of state **predicate**′ (x)

includes those participants that are crushed, killed, smashed, shattered, broken, destroyed, and so on, whereas the second argument of **predicate′** (x, y) includes those participants that are placed, moved, thrown, given, possessed, transferred, seen, heard, loved, and so on. In terms of affectedness, the former type of participant is much more affected than the latter, hence the placement of the single argument of state **predicate′** (x) at the end of the hierarchy. Into the middle of the continuum falls the first argument of **predicate′** (x, y). If it is contrasted with the first argument of **do′**, it is clear that seeing, thinking, believing, possessing, and so on are less agentlike than are speaking, doing, moving, performing, and consuming, hence their placement to the right of effector. If, on the other hand, the contrast is with the second

Table 8 RRG definitions of thematic relations in terms of LS argument positions

	Class	*Thematic relations*	*Definition of x, y*
I. State verbs			
A. Single argument	1. State or condition	**broken′** (x)	x = patient
	2. Existence	**exist′** (x)	x = entity
B. Two arguments	1. Pure location	**be-LOC′ (x, y)**	x = location, y = theme
	2. Perception	**hear′** (x, y)	x = perceiver, y = stimulus
	3. Cognition	**know′** (x, y)	x = cognizer, y = content
	4. Desire	**want′** (x, y)	x = wanter, y = desire
	5. Propositional attitude	**consider′** (x, y)	x = judger, y = judgment
	6. Possession	**have′** (x, y)	x = possessor, y = possessed
	7. Internal experience	**feel′** (x, y)	x = experiencer, y = sensation
	8. Emotion	**love′** (x, y)	x = emoter, y = target
	9. Attributive	**be′** (x, [**pred′**])	x = attributant, y = attribute
	10. Identificational	**be′** (x, [**pred′**])	x = identified, y = identity
	11. Specificational	**be′** (x, y)	x = variable, y = value
	12. Equational	**equate′** (x, y)	x, y = referent
II. Activity verbs			
A. Single argument	1. Unspecified action	**do′** (x, Ø)	x = effector
	2. Motion	**do′** (x, [**walk′** (x)])	x = mover
	3. Static motion	**do′** (x, [**spin′** (x)])	x = st-mover
	4. Light emission	**do′** (x, [**shine′** (x)])	x = 1-emitter
	5. Sound emission	**do′** (x, [**gurgle′** (x)])	x = s-emitter
B. One or two arguments	1. Performance	**do′** (x, [**sing′** (x, (y))]	x = performer, y = performance
	2. Consumption	**do′** (x, [**eat′** (x, (y))])	x = consumer, y = consumed
	3. Creation	**do′** (x, [**write′** (x, (y))])	x = creator, y = creation
	4. Directed perception	**do′** (x, [**hear′** (x, (y))])	x = observer, y = stimulus
	5. Use	**do′** (x, [**use′** (x, y)])	x = user, y = implement

Figure 1 Thematic relations continuum in terms of LS argument positions.

argument of **predicate′** (x, y), then the reverse follows: seeing, thinking, liking, believing, and so on involve some kind of internal activity (mental, emotional or perceptual) on the part of the participant, whereas being seen, being thought about, being liked, and being believed do not require any action or effort of any kind on the part of the participant. Hence, the participant referred to by the first argument is more active and, hence, more agentlike than the participant referred to by the second argument and, accordingly, the first argument is closer to the agent end of the hierarchy than the second argument. Thus, the place of the different argument positions in the continuum in Figure 1 is indicative of the semantic contrasts among them.

The second type of semantic role plays a crucial role in the theory; macroroles act as the primary interface between the LS and syntactic representations. There are only two macroroles, actor and undergoer, corresponding to the two primary arguments in a prototypical transitive relation. They are called 'macroroles' because each subsumes a number of specific thematic relations. Consider the range of thematic relations that can function as subject and direct object in English, as shown in Table 9 (the subject NPs and their thematic relation are in italics; the direct object NPs and their thematic relations are in boldface). There is a range, sometimes overlapping, of thematic relations that can serve as subject and direct object; the subject can be an agent (effector), instrument (effector), perceiver, or recipient, whereas the direct object can be a patient, theme, stimulus, recipient, source, or perceiver. The passive versions of these sentences are given in (2).

(2a) **The duckling** was killed by *the farmer*
(2b) **The window** was broken by *the* rock
(2c) **The summons** was received by *the lawyer*
(2d) **The accident** was seen by *many tourists*
(2e) **Bill** was presented with the award by *Sally*

Table 9 Thematic relations of subjects and objects in English

Sentence	*Subject relation*	*Object relation*
The farmer killed **the duckling**.	*Effector/Agent*	**Patient**
The rock broke **the window**.	*Effector/ Instrument*	**Patient**
The lawyer received **the summons**.	*Recipient*	**Theme**
Many tourists saw **the accident**.	*Perceiver*	**Stimulus**
Sally presented **Bill** with the award.	*Effector/Agent*	**Recipient**
The mugger robbed **Sam** of $50.	*Effector/Agent*	**Source**
The clown showed **the child** a trick.	*Effector/Agent*	**Perceiver**

(2f) **Sam** was robbed of $50 by *the mugger*
(2g) **The child** was shown a trick by *the clown*

The very same grouping of thematic relations that functions as the direct object in Table 9 serves as the subject in (2), and similarly, the same grouping of thematic relations that functions as the subject in Table 9 appears as the object of *by* in the passive versions. The grammatical relations are different in Table 9 and (2), and yet the groupings of thematic relations are the same. This shows that these groupings do not constitute a grammatical relation but rather another, more general type of semantic role. The role of the subject of an active voice transitive verb and the object of *by* in a passive construction is actor, and the role of the direct object of an active voice transitive verb and the subject of a passive verb is undergoer. In terms of Table 9, the thematic relations in the second column function as the actor with each of those verbs, and the relations in the third column function as the undergoer with each of them. Actor and undergoer are thus generalizations across the thematic relations in each column. The single argument of an intransitive verb is either an actor, as with verbs such as *run*, or an undergoer, as with verbs such as *die*.

The relationship between the macroroles and the argument positions in LSs is captured in the actor-undergoer hierarchy in Figure 2. The positions in the actor-undergoer hierarchy are the same LS argument positions ranked as in Figure 1. Given the LS of a verb, the most agentlike argument will be actor and the most patientlike will be undergoer, in the default case. Macroroles are not equivalent to grammatical relations, as shown in the following German examples.

(3a) Der Junge [SUBJ, ACTOR] hat den Kuchen [OBJ, UNDERGOER] aufgegessen
'The boy [SUBJ, ACTOR] ate the cake [OBJ, UNDERGOER]'
(3b) Der Kuchen [SUBJ, UNDERGOER]wurde vom Jungen [ACTOR] aufgegessen
'The cake [SUBJ, UNDERGOER] was eaten by the boy [ACTOR]'
(3c) Der Hund [SUBJ, ACTOR] ist um das Haus herumgelaufen
'The dog [SUBJ, ACTOR] ran around the house'
(3d) Der Hund [SUBJ, UNDERGOER] ist gestorben
'The dog [SUBJ, UNDERGOER] died'

Figure 2 Actor-undergoer hierarchy.

The exact role of macroroles in the mapping (or linking) between semantic and syntactic representations is discussed elsewhere (*see* **Role and Reference Grammar**).

The Lexicon

The lexicon plays a very important role in RRG, and it should be considered a lexicalist theory. Lexical entries for verbs are built around LSs; the lexical representation of nouns is based on the theory of nominal qualia proposed in Pustejovsky (1995). RRG takes the position that lexical entries for verbs should contain only idiosyncratic information, with as much as possible derived from general lexical principles or rules. Information about transitivity is very important, and RRG defines transitivity in terms of the number of macroroles that a verb takes (Narasimhan, 1998): M(acrorole)-transitive = 2, M-intransitive = 1, M-atransitive = 0. In RRG, no syntactic subcategorization information is included in lexical entries; all the relevant information is derivable from the LS of the verb plus information about its transitivity. Thus, these principles have the effect of predicting the syntactic subcategorization of a verb from its semantic representation. (See Van Valin and LaPolla, 1997, for an application of this to the analysis of syntactic issues in a wide range of languages.) All theories must specify the transitivity of exceptional verbs, and this is done in RRG by specifying their M-transitivity in terms of [MRα], where α is 0, 1, or 2. Sample lexical entries for some English verbs are given in Table 10. The prepositions that mark oblique core arguments can, in many instances, be predicted from the LS of the verb and therefore need not be listed in the lexical entry (cf. Jolly, 1993; Van Valin and LaPolla, 1997).

RRG distinguishes lexical from syntactic phenomena in terms of the linking scheme (*see* **Role and Reference Grammar**). Basically, any process that affects LSs or the arguments therein or the mapping between LSs and macroroles is considered to be lexical. Examples include causativization, regardless of whether it is morphologically unmarked (as in English) or marked (as in Japanese and Lakhota (Lakota)); noun incorporation; the 'dative alternation' (which is analyzed as variable linking to undergoer; cf. Van Valin, 1993a, 2005); and some types of passivization and antipassivization. Syntactic phenomena involve the mapping between macroroles and the syntactic representation, for example, some types of passivization and antipassivization; Wh-question formation in languages such as English and Icelandic; and 'raising' constructions (cf. Van Valin, 2005).

Table 10 Sample lexical entries for English verbs

Verb	*Lexical entry*
kill	[**do**′ (x, Ø)] CAUSE [BECOME **dead**′ (y)]
own	**have**′ (x, y)
belong (to)	**have**′ (x, y) [MR1]

The Semantics of Clause Linkage

Syntactic clause-linkage relations (*see* **Role and Reference Grammar**) are used to express certain semantic relations between the units in the linkage (e.g., causation, purpose, and temporal sequence). The interclausal semantic relations are given next.

1. Causative [1]: The bringing about of one state of affairs directly by another state of affairs, usually an event or action, for example, *Max painted the door green, Larry pushed the window open*.
2. Phase: A separate verb describes a facet of the temporal envelope of a state of affairs, specifically its onset, its termination, or its continuation, for example, *Chris started crying, Fred kept singing, Hari finished writing the chapter.*
3. Modifying subevents
   - Manner: The manner in which a motion event is carried out, for example, *Bill entered the room skipping*.
   - Motion: Motion accompanying another action, for example, Mparntwe Arrente (Wilkins, 1991):

     angk-tyantye-
     speak-go.upward
     'speak while going up'.

   - Position: Stance while doing an action, for example, *Dana sat reading a newspaper.*
   - Means: The means by which an action is carried out, for example, *Sam opened the box by slicing it with a knife*.
4. Psych-action: A mental disposition regarding a possible action on the part of a participant in the state of affairs, for example, *Max decided to leave, Sally forgot to open the window, Tanisha wants to go to the movies*.
5. Purposive: One action is done with the intent of realizing another state of affairs, for example,

Juan went to the store to buy milk, Susan brought the book to read.

6. Jussive: The expression of a command, request, or demand, for example, *Pat asked the student to leave, the king ordered the troops to attack the city.*
7. Causative [2]: The bringing about of one state of affairs through a distinct action or event, for example, *Fred forced Max to paint the table.*
8. Direct perception: An unmediated apprehension of some act, event, or situation through the senses, for example, *Rex saw the child open the door, Yolanda heard the guests arrive.*
9. Indirect perception: The deduction of some act, event, or situation from evidence of it, for example, (looking at an empty desk) *I see that John has gone home early.*
10. Propositional attitude: The expression of a participant's attitude, judgment, or opinion regarding a state of affairs, for example, *Carl believes that UFOs are a menace to the Earth, Paul considers Carl to be a fool, most fans want very much for their team to win.*
11. Cognition: An expression of knowledge or mental activity, for example, *Aaron knows that the Earth is round, George is thinking about Madeleine's refusal to go out with him.*
12. Indirect discourse: An expression of reported speech, for example, *Frank said that his friends were corrupt.*
13. Direct discourse: The direct quotation of a speech event, for example, *Frank said, "My friends are corrupt."*
14. Circumstances: The spatial or temporal parameters of an event, for example, *Sam talked to Sally at the library after work.*
15. Reason: The motivation or cause for an action or event, for example, *The baby cried because she was hungry.*
16. Conditional: An expression of what consequence would hold, given the conditions in a particular state of affairs, for example, *if it rains, we won't be able to have a picnic*; *were Fred to leave now, he would look like a fool.*
17. Concessive: The content of the main clause holds unexpectedly, given the content of the subordinate clause, for example, *Bill made it to work, even though it was snowing heavily.*
18. Temporal
    - Simultaneous states of affairs: One state of affairs is temporally coterminous with another, for example, *Max danced, and at the same time Susan played the piano.*
    - Sequential states of affairs: One state of affairs follows another temporally, with or without any temporal overlap, for example, *Juan had finished talking, and then Carlos entered the room.*
19. Temporally unordered states of affairs: The temporal relation between states of affairs is unexpressed, for example, *Tyrone talked to Tanisha, and Yolanda chatted with Kareem.*

These relations may be given a formal characterization in terms of the RRG decompositional system, following a suggestion of Ohori (2001). This is presented in Table 11. In this table, Causative [1] has the same LS as a lexical causative verb, as in the causative examples in Table 5, whereas Causative [2] involves a matrix LS, the LS of an overt causative verb and an embedded LS, as in *Kim forced Chris to wash the dishes*. See Jolly, 1993, for an explication of the purposive LS. '(x, [LS . . . x . . .])' means that the participant denoted by *x* is involved in both states of affairs signaled by the matrix and embedded LSs. The *x*

[a] ∧ means 'and simultaneously'; & means 'and then'; + indicates temporally neutral coordination; ◇ means possibly.

Figure 3 Interclausal semantic relations hierarchy.

Figure 4 Interclausal relations hierarchy.

argument in Table 11 example (j) is optional because some propositional attitude predicates are one-place and take only a propositional argument (e.g., *be true, be false, be certain*). The contrast between direct and indirect discourse is signaled by the existence of an illocutionary force operator in the embedded LS in direct discourse and by the lack of one in the embedded LS in indirect discourse.

The semantic relations form a continuum expressing the degree of semantic cohesion between the propositional units linked in the complex structure, that is, the degree to which they express facets of a single action or event or discrete actions or events. This may be represented as in Figure 3.

The syntactic linkage relations may be ranked hierarchically in terms of the strength of the syntactic bond between the units, that is, in terms of how integrated the units are into a single unit or are coded as distinct units. The interaction of the two hierarchies is expressed in the interclausal relations hierarchy in Figure 4. The relationship between the syntactic and semantic relations in clause linkage is very complex – it is not one to one – but there are some striking regularities cross-linguistically. The primary principle governing the interaction of the two hierarchies is: the closer the semantic relation between two propositions, the stronger the syntactic link joining them is (Silverstein, 1976; Givón, 1980). In other words, the semantic relations at the top end of the hierarchy should be realized by the linkage categories at the top as well, and the relations at the bottom of the hierarchy should be realized by the linkage categories at the bottom of the syntactic side. Moreover, although there is often more than one syntactic realization of a particular semantic relation, the tightest syntactic linkage realizing it should be tighter than the tightest syntactic linkage realizing looser semantic relations.

Semantics of Interrogatives

B Sherman, Princeton University, Princeton, NJ, USA

© 2006 Elsevier Ltd. All rights reserved.

Many problems in semantics are typically expressed as problems about how to define a function from the form of a sentence to the conditions in which the sentence can be uttered truly (or, alternatively, to a proposition that can be expressed by an utterance of the sentence). The main problem posed by interrogatives for the truth-conditional approach to semantics is rather different. They do not give rise to a problem of how to map a function from the form of a sentence to its truth conditions. Rather, they give us reason to suspect that there is no such function. For interrogatives, unlike indicatives, do not seem to have truth conditions, and nor do they seem to express propositions that themselves have truth conditions. The main problem interrogatives pose is metasemantic: to say what a semantics for interrogatives must do.

In the 'Metasemantics' section of this article, I survey three attempts to deal with this question. In the 'Semantics' section, I present some basic-level semantic questions that would need to be addressed even if the metasemantic question were settled – though in all probability they will in fact **help** us to settle the metasemantic question.

Metasemantics

Above, I introduced one constraint on choosing a semantic framework for interrogatives: interrogative sentences are not true or false, so we should not assign to them some semantic object that is true or false, at least not without further explanation. Another is the Davidsonian constraint of 'semantic innocence': the fixed meaning of a word should not vary with the environment in which it occurs. This constraint generates a tension with any approach to the metasemantic problem that ignores the truth-conditional approach that works so nicely for indicative sentences. For this reason, the three dominant frameworks that I will focus on all treat the semantics of interrogatives in broadly truth-conditional terms. That is, in all of the frameworks to be discussed here, the meaning of an interrogative is in some way tied to a propositional object of some sort. In the rest of this section, I will look at the following three approaches to

Many problems in semantics are typically expressed as problems about how to define a function from the form of a sentence to the conditions in which the sentence can be uttered truly (or, alternatively, to a proposition that can be expressed by an utterance of the sentence). The main problem posed by interrogatives for the truth-conditional approach to semantics is rather different. They do not give rise to a problem of how to map a function from the form of a sentence to its truth conditions. Rather, they give us reason to suspect that there is no such function. For interrogatives, unlike indicatives, do not seem to have truth conditions, and nor do they seem to express propositions that themselves have truth conditions. The main problem interrogatives pose is metasemantic: to say what a semantics for interrogatives must do.

In the 'Metasemantics' section of this article, I survey three attempts to deal with this question. In the 'Semantics' section, I present some basic-level semantic questions that would need to be addressed even if the metasemantic question were settled – though in all probability they will in fact **help** us to settle the metasemantic question.

Metasemantics

Above, I introduced one constraint on choosing a semantic framework for interrogatives: interrogative sentences are not true or false, so we should not assign to them some semantic object that is true or false, at least not without further explanation. Another is the Davidsonian constraint of 'semantic innocence': the fixed meaning of a word should not vary with the environment in which it occurs. This constraint generates a tension with any approach to the metasemantic problem that ignores the truth-conditional approach that works so nicely for indicative sentences. For this reason, the three dominant frameworks that I will focus on all treat the semantics of interrogatives in broadly truth-conditional terms. That is, in all of the frameworks to be discussed here, the meaning of an interrogative is in some way tied to a propositional object of some sort. In the rest of this section, I will look at the following three approaches to

the metasemantic problem: the force/radical approach, the epistemic-imperative approach, and the question-as-answer approach.

According to the force/radical approach, sentences can be factored into two components: a force indicator and a propositional radical. Roughly, the propositional radical supplies the truth-conditional content to the sentence, and the force indicator suggests the attitude taken toward that content. So, on this approach, advanced by McGinn (1977), Davidson (1984), and Stainton (1999), sentences (1) and (2) have the same radical and different moods:

(1) The monkey is hungry.

(2) Is the monkey hungry?

The mood of the sentence indicates the force of a typical utterance of the sentence. Sentences in the indicative mood are typically used for asserting the proposition expressed by the radical. Sentences in the interrogative mood are typically used to ask whether the proposition expressed by the radical is true.

This picture works well for yes/no questions, such as (2). What about wh-questions, such as (3)?

(3) What does the monkey want?

The radical of (3) could be thought of as a propositional function of the form in (4):

(4) λx: the monkey wants x

Some story would then be needed to explain why attaching an interrogative mood to (4) would yield the desired interpretation. In addition, it seems like the only mood one could attach to (4) is the interrogative mood. This seems out of character with the general approach, which emphasizes the possibility of attaching different moods to the same radical, thus requiring some explanation if the approach is to be defended.

The epistemic-imperative approach treats the meaning of an interrogative as an imperative concerning one's epistemic state. Sentence (2) would be analyzed as meaning what (5) means, and (3) would be analyzed as meaning what (6) means.

(5) Let it be the case that (or: Bring it about that) I know whether the monkey is hungry.

(6) Let it be the case that (or: Bring it about that) I know what the monkey wants.

On this approach, advocated by Åqvist (1965) and Hintikka (1983), the direct interrogative exemplified by (2) and (3) is analyzed in terms of the indirect interrogative contained in (5) and (6). In order for this approach to provide a semantic framework for interrogatives, an account of the semantics of indirect interrogatives is needed.

Hintikka gave an analysis of 'know whether' in terms of 'know that.' Sentence (5) on this analysis would be equivalent to (7):

(7) Bring it about that either I know that the monkey is hungry, or I know that the monkey is not hungry.

However, this analysis of indirect interrogatives faces difficulties when embedded under verbs such as 'wonder':

(8) I wonder whether the monkey is hungry.

Sentence (8) does not seem susceptible to a similar sort of paraphrase, causing trouble for any view that attempts to analyze away the indirect interrogative.

Finally, the question-as-answer approach treats the interrogative, either direct or indirect, as denoting a question, where this is understood to be a special sort of semantic object. Since a question determines a set of answers, the set of answers is used as a surrogate object for the question (much in the way that a set of possible worlds is used as a surrogate object for propositions). The intuitive idea motivating this approach, originating in Hamblin (1958), is that to know the meaning of a question is to know what counts as an answer to it. Different versions of the approach differ in which set of answers is used.

On the most standard version of this approach, advanced by Hamblin (1958) and Groenendijk and Stokhof (1994), the meaning of an interrogative should be thought of as the set of possible answers to a question, where this set of possible answers forms a partition of logical space. Every possible answer on this view is a complete answer to the question, and the set of answers jointly exhausts the possibilities of complete answers.

Karttunen (1977) provided two reasons for treating the meaning of an interrogative as the set of its true, rather than possible, answers. First, consider sentence (9):

(9) Who is elected depends on who is running.

According to Karttunen, this sentence says that the true answer to the subject position question depends on the true answer to the object position question. So treating the meanings of interrogatives as sets of true answers provides a more straightforward account of verbs such as 'depend on.' Second, consider sentences (10) and (11):

(10) John told Mary that Bill and Susan passed the test.

(11) John told Mary who passed the test.

Sentence (11) entails that John told Mary the truth, whereas this is not the case with sentence (10). By treating the indirect interrogative in (11) as denoting a set of true answers, this entailment is straightforwardly explained.

Karttunen's account has some counterintuitive consequences, however. For example, somebody who asks question (2) in a situation where the monkey is hungry intuitively asks the same question as somebody who asks question (2) in a situation where the monkey is not hungry. But on Karttunen's account, the meaning of the questions asked in the two situations is different, since the true answers to the questions asked are different.

A more general worry with the question-as-answer approach, articulated by Stainton (1999), is that it makes the domain of the interrogative – the set of objects that figure in the possible answers to it – a part of its meaning. It seems intuitive that one can understand a question without knowing anything about the objects that figure in the possible answers to it. For example, if an alien from outer space lands on Earth, we might ask the question 'What does the alien want?' Surely, among the possible answers to this question are objects that we've never seen or imagined before. But that doesn't stop us from understanding the meaning of the question, as it seems it should on the question-as-answer approach.

Although the approaches to the metasemantic problem presented here are dominant in the literature, they are by no means exhaustive. Ultimately, the success of a given framework will depend on the extent to which it is successful in accounting for various semantic phenomena.

Semantics

One of the ongoing semantic debates in the semantics of interrogatives concerns the ambiguity that results from a wh-question containing a universal quantifier, as in (12):

(12) Who does everyone like?

According to one reading of (12), the question is asking which people are such that every person likes them. An appropriate answer might be, for example, 'Bill and Mary.' On the other reading of (12), the question is asking which person each person likes. An appropriate answer to this question would be a list of pairs of people of the form 'Bill likes Mary, Mary likes Sue, Sue likes Bill.' The debate specifically concerns this second reading of the question, called the pair/list reading. The question is how to account for that reading semantically.

There have been two main sides to the debate. According to one standard view, the role of the quantifier that occurs in the interrogative is to restrict the domain of the question. So (12) could be paraphrased roughly as (13):

(13) For every person, who does that person like?

Exactly how this paraphrased reading is derived from (12) will depend in large part on the metasemantic approach that one favors. For example, Groenendijk and Stokhof (1984) modified Karttunen's metasemantic approach in implementing their view.

According to an alternative view, pair/list readings are an instance of a more general kind of reading. Consider the following question/answer pair in (14):

(14a) Who does every man love?
(14b) His mother.

The answer in (14) gives rise to a functional reading of the question. The answer to the question is not an individual, but a function – that is, a rule which takes one from an object to another object. Pair/list readings are, according to this alternative, functional readings, where the function is specified extensionally, in terms of the ordered pairs in the extension of the function. This view was presented in Engdahl (1985) and developed by Chierchia (1993). Accounting for functional readings is an interesting semantic issue in its own right. For alternative accounts of pair/list readings, see Beghelli (1997), Szabolcsi (1997a), and Pafel (1999).

Another semantic issue concerns the nature of the presuppositions that different sorts of questions give rise to. For example, the question 'What is it like owning a monkey?' presupposes that the addressee owns a monkey. The question 'Who came to the party?' presupposes that someone came to the party. The question 'Which monkey ate the banana?' presupposes that a unique monkey ate the banana. Whether these presuppositions are semantic in nature and, if so, where they arise from has been a contested issue. See Belnap and Steel (1976), Karttunen (1977), Higginbotham and May (1981), and Hintikka (1983).

A final semantic issue that is of both linguistic and philosophical interest concerns the context sensitivity involved in whether something counts as an answer to a question. This issue is particularly pressing for the question-as-answer approach, since most versions of that approach assume that each question has some unique complete answer. Ginzburg (1995) developed a novel account of the semantics of interrogatives aimed at accommodating various sorts of context sensitivity. In general, questions calling for the identification of something seem to be interest relative. For

example, the sentence 'Where am I?' might be used to ask for the country in which one is located, the street on which one is located, the room in which one is located, etc. In some situations, one counts as knowing who killed Lady Chittlesworth when one knows simply that the murderer is the person that was wearing the yellow shirt. In other situations, this would not count as an acceptable answer. See Boër and Lycan (1985) for an account of knowing who someone is.

This brief survey of issues is far from exhaustive. For a very useful overview of both metasemantic approaches to interrogatives and semantic issues concerning interrogatives, see Groenendijk and Stokhof (1994).

From the speaker's perspective, 'intonation' is the systematic variation in rate of vocal fold vibration that cannot be attributed to lexical properties of words (lexical tone) or to effects that are a result of consonants or vowels ('microprosody'). In more recent discussions of intonational meaning, a distinction is generally drawn between 'linguistic meaning,' which is associated with the structural elements making up the intonation contour, and 'paralinguistic meaning,' which derives from the way an intonation contour is pronounced (e.g., Ladd, 1996). The first section of this article discusses linguistic meaning and identifies three aspects of the structure that contribute to that meaning, phrasing, pitch accent distribution, and pitch accent type. The following section discusses paralinguistic meanings and links these to physiological conditions in the speech production process which have an effect on the rate of vocal fold vibration.

Linguistic Meaning

There are three aspects of the prosodic structure that can convey meaning: prosodic phrasing, pitch accent location, and type of pitch accent or melody. 'Prosodic phrasing' is the division of utterances into word groups, whereby smaller word groups can be distinguished within larger word groups ('prosodic hierarchy'). The difference between {*To govern, people use language*} and {*To govern people, use language*} illustrates a difference in 'intonational phrasing,' while that between {*They'll award*} {*Áberdéen*} {*Architecture*} (i.e., during a centralized redistribution of academic disciplines over universities) and {*They'll award*} {*Áberdeen árchitecture*} (i.e., give a prize to) illustrates a difference

example, the sentence 'Where am I?' might be used to ask for the country in which one is located, the street on which one is located, the room in which one is located, etc. In some situations, one counts as knowing who killed Lady Chittlesworth when one knows simply that the murderer is the person that was wearing the yellow shirt. In other situations, this would not count as an acceptable answer. See Boër and Lycan (1985) for an account of knowing who someone is.

This brief survey of issues is far from exhaustive. For a very useful overview of both metasemantic approaches to interrogatives and semantic issues concerning interrogatives, see Groenendijk and Stokhof (1994).

From the speaker's perspective, 'intonation' is the systematic variation in rate of vocal fold vibration that cannot be attributed to lexical properties of words (lexical tone) or to effects that are a result of consonants or vowels ('microprosody'). In more recent discussions of intonational meaning, a distinction is generally drawn between 'linguistic meaning,' which is associated with the structural elements making up the intonation contour, and 'paralinguistic meaning,' which derives from the way an intonation contour is pronounced (e.g., Ladd, 1996). The first section of this article discusses linguistic meaning and identifies three aspects of the structure that contribute to that meaning, phrasing, pitch accent distribution, and pitch accent type. The following section discusses paralinguistic meanings and links these to physiological conditions in the speech production process which have an effect on the rate of vocal fold vibration.

Linguistic Meaning

There are three aspects of the prosodic structure that can convey meaning: prosodic phrasing, pitch accent location, and type of pitch accent or melody. 'Prosodic phrasing' is the division of utterances into word groups, whereby smaller word groups can be distinguished within larger word groups ('prosodic hierarchy'). The difference between {*To govern, people use language*} and {*To govern people, use language*} illustrates a difference in 'intonational phrasing,' while that between {*They'll award*} {*Áberdéen*} {*Architecture*} (i.e., during a centralized redistribution of academic disciplines over universities) and {*They'll award*} {*Áberdeen árchitecture*} (i.e., give a prize to) illustrates a difference

in 'phonological phrasing.' Two comments are in order here. First, a direct reflection of syntactic structure in prosodic structure may be upset by the length of constituents. For instance, if there is only a single word after *award* in the first of the last two examples, it would form a single phonological phrase with the verb, as in {*They'll award Aberdéen*}. Second, many languages require that the 'focus constituent' – the part of the sentence which the speaker intends to contribute as the new information – should begin or end at a prosodic phrase boundary. Thus, for example, Bengali ends the focus constituent with a phonological phrase boundary, regardless of the syntactic phrase structure, and while {*Shamolir bari*} 'Shamoli's house' could be an answer to 'What's that?', {*Shamolir*} {*bari*} implies a question: 'Whose house?' In a similar way, many languages, English among them, use pitch accents to convey information structure. Information structure concerns the status of the propositional information contained in the focus constituent relative to what the speaker assumes the hearer already knows. This need not be confined to marking 'newness,' as in the Bengali example, but also includes the status of the proposition as a description of a real event, as shown by *THIEVES will be PROSecuted* versus *THIEVES will be prosecuted*. In the second sentence, the absence of a pitch accent on the verb does not signify it is meant to be 'old' information, but causes the proposition to describe an upcoming event (cf. Gussenhoven, 2005).

Approaches to linguistic meaning of speech melody, the third structural aspect of prosody, can be distinguished on the basis of the size of the meaning-bearing (melodic) morpheme, which in principle ranges from a single tone (high or low) to the whole contour. The most fine-grained morphemic structure was proposed by Pierrehumbert and Hirschberg (1990), for whom each pitch accent and each boundary tone is a morpheme, and the most coarse-grained one by Liberman and Sag (1974) and Sag and Liberman (1975), who saw utterance-wide contours as morphemes. Intermediate positions were proposed in the mid-1970s by Brazil (1985), followed by Gussenhoven (1984), both of whom attached meanings to nuclear tones, i.e., combinations of pitch accents and boundary tones.

Consensus would appear to have been reached on the issue of whether the meaning of an intonation contour can be described independently of the meaning of the sentence it is used with, with Ladd's (1978: 139) 'lexical' approach to intonational meaning. Intonational meaning has alternatively been viewed as something that can only be characterized in combination with sentence type, which Cruttenden (1996: 91) refers to as 'local' meaning, where the suggestion is that a common element may be difficult or impossible to isolate from the meanings of a given tune in declaratives, questions, commands, etc. There is widespread agreement that intonational morphemes in fact have 'lexical' meaning and that this concerns discourse structure or information structure, rather than speech acts (e.g., Sag and Liberman, 1975) or speaker attitudes (e.g., O'Connor and Arnold, 1973). That is, intonational morphemes typically do not mean 'promise' or 'skepticism,' but rather define the way the speaker intends the proposition to be fitted into what he believes the hearer already knows at that point in their conversation (Brazil, 1985; Gussenhoven, 1984), or, as Pierrehumbert as Hirschberg (1990: 285) put it, "speakers use tunes to specify a particular relationship between the 'propositional content' [...] and the mutual beliefs of participants in the current discourse." For instance, the falling-rising tune of English has been characterized as somehow reactivating information by several authors (e.g., Brazil, 1985; Steedman, 1991), while the falling tune conveys that the information is new. In this view, the melodic meanings and the meanings conveyed by pitch accent distributions come from the same class. Since morphemes are acquired, they may and often do differ from language to language. For example, a pattern such as the English declarative fall signifies a question in Chickasaw (Gordon, 2003), and the number of languages in which rising pitch is regularly used for statements must be fairly large (Bolinger, 1978).

Paralinguistic Meaning

Just as segment duration and voice quality can be varied for expressive purposes (e.g., *How sa-ad!* or *I want it!* said with breathy voice) without changing the identity of the linguistic expression, so can pitch be varied, independent of the identity of the intonation contour. 'Pitch span,' the distance between the highest and the lowest pitch, and 'pitch register,' the average pitch of the contour, can be varied to express such meanings as insistent, sad, confident, etc. Relating pitch to the size of the larynx, and hence to the size of the creature that possesses it, Ohala (1983, 1996) extended the explanation for the widespread similarities among avian and mammalian vocalizations in face-to-face competitive encounters to human speech. Vocalizations by dominant individuals are low-pitched, suggesting a large creature, while those by subordinate individuals are high-pitched, suggesting a small creature. In speech, high and rising pitch is used to signal yes-no questions, while low and falling pitch signals statements. For Ohala, high pitch expresses that the speaker is

dependent on the other's good will for the information requested – but making statements implies certainty, hence dominance. Metaphorical extensions are politeness, submission, lack of confidence vs. assertiveness, authority, aggression, confidence, and threat.

Paralinguistic meanings may be seen as more or less metaphorical interpretations of three physiological conditions that influence the rate of vocal fold vibration, the main determinant of voice pitch. One of these is Ohala's 'frequency code' (Gussenhoven, 2004: ch 5). A second condition affecting rate of vocal cord vibration is degree of effort. The 'effort code' relates wide excursions, and generally precision in the articulation, to the expenditure of energy, and hence with importance, emphasis, and obligingness. Third, the physiological condition underlying the 'production code' is the exhalation phase of the breathing process used for speech production, and the way it leads to a fall-off in subglottal air pressure toward the end of the utterance, associating high pitch with utterance beginnings and low pitch with utterance endings. High beginnings thus signal new topics and low beginnings continuation of topics, while high endings signal continuation and low endings finality and end of turn. The effects of these conditions have to a large extent been brought under speaker control. Even derived effects, such as the later realization of higher peaks relative to lower peaks, may be exploited such that later peaks are used to signal the meanings of higher peaks. For instance, in many languages, early peaks signal statements and later peaks signal questions (e.g., D'Imperio and House, 1997).

In view of their biological basis, it is not surprising that paralinguistic form-meaning relationships are exploited across groups of speakers with different language backgrounds in strikingly similar ways. Nevertheless, crosslinguistic perception research suggests that the structure of the native language, along with phonetic factors such as the average pitch span, influence the listener's sensitivity (Chen, 2005). For instance, speakers of languages with narrower pitch spans may perceive greater meaning differences across a given pitch span than speakers of language with wider average pitch spans.

Whereas linguistic meaning is discrete – in the sense that if a language has two intonational morphemes (high-low and low-high, for instance), any well-formed utterance has either one or the other – paralinguistic meaning is gradient. A paralinguistic meaning is more or less present, depending on the value of the relevant pitch variable: the wider the span, the more effort is suggested, and the higher the register, the more submissiveness will be expressed.

Semantics of Spatial Expressions

J Zlatev, Lund University, Lund, Sweden

© 2006 Elsevier Ltd. All rights reserved.

Introduction

Spatial semantics has been an extremely active area of research in the past few decades, particularly within the field of cognitive linguistics (Langacker, 1987; Lakoff, 1987), in which spatial meaning is envisioned as standing at the very core of language and cognition. In a broader context, however, spatial semantics research is riddled with many controversies. It has long been known that there are strong parallels between space and other semantic domains, reflected in the fact that the same linguistic expressions often take spatial, temporal, and other more abstracts meanings, as in *from here to there*, *from now to tomorrow*, or *from me to you* (Clark, 1973). One explanation of this parallelism is conceptual metaphor, understood as a systematic asymmetric mapping between two experiential domains (Lakoff, 1987; Johnson, 1987). Since space appears to be the more concrete domain, the cognitive hypothesis is that "abstract domains are consistently conceptualized in terms of spatial image schemata" (Kreitzer, 1997: 317). However, other possible explanations of this analogy are historical processes involving grammaticalization (Heine *et al.*, 1991) and fundamental properties of mental representation (Jackendoff, 1990).

The Scope of Spatial Semantics

A common way of defining spatial semantics is by assuming a particular expression class – e.g., closed-class forms (Talmy, 1983) or spatial grams (Svorou, 1994). As Svorou (1994: 31) stated, "To talk about space and spatial relations . . ., languages make use of a relatively small number of elements. . . . I will refer to all these grammatical forms of language which express primarily spatial relations as *spatial grams*." However, this approach lacks the means to distinguish spatial from non-spatial senses and it aprioristically limits the domain of analysis to an expression class that is by no means universal (Brown, 1994).

An alternative is to define spatial language as expressions of spatial relations (Talmy, 1983; Regier, 1996). This semantic category assumes the semantic primitives 'trajector' and 'landmark,' whereby the location or motion of the first is characterized in terms of its relationship to the second (see later). Again, this approach is not general enough because different languages employ different strategies of locating objects in space, and not all are equally relational (Kreitzer, 1997). In English, we can readily characterize the meaning of the utterance in Example (1a) in terms of a trajector–landmark relation, and this can also be extended to Example (1b), assuming an elliptic/implicit landmark. To offer a similar analysis for Examples (2a) and (2b), however, we need to postulate landmarks of a different sort, e.g., 'the sky' and 'the speaker':

(1a) The plane flew over the house.
(1b) The plane flew over.

(2a) The plane flew upwards.
(2b) The plane flew this way.

Such an analysis, however, misses an important distinction: Examples (2a) and (2b) not only lack the explicit landmark as in Example (1b), but do not require one, since the trajector's position is determined not through objectlike reference points, but through coordinate systems (see later, Frame of Reference). A possibility would be to exclude sentences such as those in Examples (2a) and (2b) from the subject matter of spatial semantics proper, but this would be both arbitrary and ethnocentric, considering the basically relational meaning of Indo-European adpositions.

A third way of defining spatial semantics is through communicative function, i.e., the meanings of utterances that help the addressee determine the location or translocation of a given referent in discourse (Zlatev, 1997; Levinson, 2003). This definition intuitively excludes (metaphorical) extensions such as the utterance in Example (3), but includes the problematic (Examples (2a) and (2b)):

(3) He is over his divorce.

(4) He seems to be washing the dishes. [Where is he?]

Those who wish to assign spatial semantics to literally non-spatial uses would object to this (Lakoff, 1987), but it does provide a principled basis for constraining the domain of study. However, utterances such as in Example (4) can serve a locative communicative function indirectly, but we would hesitate before regarding them as 'spatial.' Thus, we must add the requirement that the locative function needs to be expressed conventionally: spatial expressions are conventional specifications of the location or the change of location (i.e., translocation) of an object.

Basic Spatial Semantic Concepts

A multitude of spatial categories have been proposed as 'universals' or 'primitives' in the literature, and

describing them all would be prohibitive. However, seven spatial concepts, trajector, landmark, frame of reference, path, region, direction, and motion, are present in nearly all descriptive systems. Authors may use different terms and make different distinctions, but the bare fact that there seems to be almost full agreement on the essentiality of these concepts is significant.

Trajector

The trajector is the entity for which (trans)location is of relevance (Lakoff, 1987; Regier, 1996). The trajector may be either static (Example (5a)) or dynamic (Example (5b)), a person or an object (Example (5c)); it can also be a whole event, as in Example (5d):

(5a) *He* is in the house.
(5b) *He* went into the house.
(5c) *The ball* is on the ground.
(5d) *He is playing* inside the house.

Other terms used for the same concept are the gestalt-psychological notion of 'figure' (Talmy, 1983; Levinson, 2003) and the more general term, 'referent' (Miller and Johnson-Laird, 1976).

Landmark

The landmark is the reference entity in relation to which the (trans)location of the trajector is specified. Views differ, however, on whether a landmark is always involved in a spatial predication as discussed in connection with the preceding problematic Examples (2b) and (2c). Similar lack of clarity exists about the use of other parallel terms, i.e., 'ground' (Talmy, 1983; Levinson, 2003) and 'relatum' (Miller and Johnson-Laird, 1976). For example, is there a landmark/ground/relatum in the simple everyday utterance in Example (6), and, if so, what is it?

(6) Come here!

For Langacker (who initiated the systematic use of the terms), trajector and landmark refer to extremely general notions that are not confined to (and are not projections from) the spatial domain: "The trajector/landmark asymmetry is fundamental to relational predicates and underlies the universal subject/object distinction" (Langacker, 1987: 231). So it is not surprising that in his analyses, any kind of 'point of reference' can serve as a landmark, but that would abolish the distinction between Examples (1) and (2), as pointed out.

Frame of Reference

A spatial concept that has received considerable attention lately is that of a linguistic frame of reference (FoR). However, although almost all authors acknowledge its importance, practically no two define it in the same way. In the most general sense, a FoR defines one or more reference points, and possibly also acoordinate system of axes and angles. Depending on the types of the reference points and coordinates, different types of FoRs can be defined. A strong claim is that "there are exactly three frames grammaticalized or lexicalized in language" (Levinson, 1996: 138):

- Intrinsic: the main reference point coincides with the landmark, and axes and angles are projected on the basis of its geometry.
- Relative: a real or imaginary viewpoint serves as a reference point, and coordinates are projected on the basis of this viewpoint.
- Absolute: the system is anchored in fixed geocardinal positions.

Spatial expressions defined on the basis of these FoRs have different logical properties: intrinsic and absolute expressions are binary, whereas the relative is ternary, as shown in Figure 1. The relative and the absolute FoRs support transitive and converse inferences, but the intrinsic FoR does not. A limitation of Levinson's trichotomy, however, is that it is systematically applied only to the static projective relations on the horizontal plane. So when it is claimed that there are languages that do not use the absolute FoR, this does not deny that the absolute FoR is used for terms that refer to the vertical dimension. Zlatev (1997) attempted a generalization of the trichotomy using the terms 'allocentric,' 'deictic,' and 'geocentric,' respectively. Still, this analysis is problematic because it confounds the type of FoR with landmark type;

Figure 1 The three different linguistic frames of reference (FoR) proposed by Levinson (1996, 2003): intrinsic (binary, non-transitive), relative (ternary, transitive), and absolute (binary, transitive, and converse).

Levinson (1996: 135) correctly insisted that "linguistic frames of reference cannot be defined with respect to the origin of the co-ordinate system." For example, Examples (7a) and (7b) employ a relative FoR despite different kinds of origins, whereas Examples (8a) and (8b) use different FoRs, even though in both cases the origin (O) of the frame is the speaker:

(7a) He is standing in front of the tree.
(FoR: Relative; O: Speaker)
(7b) He is standing in front of the tree from John's point of view.
(FoR: Relative; O: John)

(8a) Stand behind the tree.
(FoR: Relative; O: Speaker)
(8b) Stand behind me.
(FoR: Intrinsic; O: Speaker)

A generalization seems nevertheless to be possible: a viewpoint-centered FoR as in Examples (7a), (7b), and (8a) need not have the speaker (or the addressee) as origin, and thus may not be, properly speaking, 'deictic.' Nevertheless, utterances such as in Examples (2b) and (6) can be subsumed under this notion, with the clarification that they (1) do not involve any angles and coordinates but only a reference point and (2) are binary rather than ternary. The binary senses are conceptually simpler and unsurprisingly are acquired earlier. What is common to both (binary and ternary) types is that the location or motion of the trajector is not defined in relation to a landmark, as, e.g., in Example (8b), but rather in relation to a viewpoint.

The object-centered FoR, on the other hand, always involves a landmark, and can be either projective (i.e., 'intrinsic'), as in Example (8b), or non-projective (topological), as in Example (5). Finally, the geocentric FoR can involve either the horizontal or the vertical plane, and, as with the other two, can be generalized to both static and dynamic descriptions (Examples (2a) and (9a)):

(9a) Go West! FoR: GEOCENTRIC
(9b) Go toward the setting sun! FoR: OBJECT-CENTERED

As the viewpoint-centered FoR, the geocentric one does not rely on a landmark in order to locate the trajector, but does so through the fixed geocardinal positions, which distinguishes Example (9a) from Example (9b).

This analysis captures the generalization that there are exactly three linguistic frames of reference and that some linguistic forms 'specialize' for frame, whereas others may be ambiguous, and still others may 'conflate' two frames. But this analysis differs in predicting that all languages use all three frames, although for different expressions, and to different degrees in discourse. The same utterance can express all three FoRs as in Example (10), displaying the flexibility of language and the power of semantic compositionality:

(10) He	came	up	to	the second floor.
	FoR:	FoR:	FoR:	
	VIEWPOINT-C	GEOCENTRIC	OBJECT-C	

Region

Even with an object-centered FoR and a (true) landmark, languages do not relate the trajector and landmark directly, but through a region that can be defined as a configuration of space in relation to that landmark (Svorou, 1994; Zlatev, 1997). Talmy (2000) invented the term 'conformation' for essentially the same notion. Jackendoff (1990) captured this distinction with the notions of thing and place, two of his semantic primitives, stating that, e.g., spatial prepositions such as *in* express place-functions: [IN ([THING])]→ [PLACE]. Figure 2 shows the regions lexicalized by a number of Japanese locative nouns, which apart from region also specify one or more frames of reference.

Jackendoff (1990) held that the set of such regions or place-functions is universal, but this is doubtful. Rather, all languages appear to make use of the concept, but they can differ both with respect to the extension of the regions that they express and whether they use primarily functional or perceptual properties of the landmark in order to define the relevant region. If such variation is granted, then arguments against the universal applicability of the

Figure 2 Japanese locative nouns expressing the spatial semantic category *region*. FoR, Field of reference. Reprinted from Zlatev (1997), with permission.

concept (Bowerman, 1996) can instead be interpreted as a characterization of its possible variation.

Path

The concept of path is used in spatial semantics in two very different ways. The first and more common may be called 'imagistic' and refers to the trajectory of actual or imagined motion of the trajector with respect to the landmark (Talmy, 1983; Lakoff, 1987). This trajectory may be schematic, but it has both extension and shape. The alternative is based on the cross-linguistic generalization that languages systematically distinguish between (at least) three components of a motion event – its beginning, its middle, and its end – and may be called the 'minimal path' characterization (Jackendoff, 1990; Zlatev, 1997). On this view, trajectories, are derived compositionally, by combining the minimal path information (e.g., END) with the region/place information (e.g., INTERIOR) to derive the meaning of a preposition such as *into*. English and other Indo-European languages contain many words, mostly prepositions, that conflate the concepts of region and path, but from a broader perspective, many if not most languages separate the two categories (Heine *et al*., 1991). Talmy (2000) arrived at the same conclusion, and currently distinguishes between the 'conformation,' corresponding to region as mentioned previously, and the vector, which "comprises the basic types of arrival, traversal and departure that a Figural schema can execute with respect to the Ground schema" (Talmy, 2000: II, 53).

Even for English, separating region and path allows for generalizations, such that the sentences in Examples (11a)–(11d) have the same value for region, but different ones for path. Including ZERO (no extension) as a possible value of path is consistent with the structure of locative case systems in, e.g., Slavonic and Finno-Ugric languages:

(11a)	Bill went out from the house.	Region: INTERIOR; Path: BEGINNING
(11b)	Bill went through the house.	Region: INTERIOR; Path: MIDDLE
(11c)	Bill went into the house.	Region: INTERIOR; Path: END
(11d)	Bill is in the house.	Region: INTERIOR; Path: ZERO

Direction

If path is defined minimally, then it always requires the category region in order to express the (trans) location, and region always requires a landmark. But since all reference points are not of the same kind, they should not be lumped under the cover term 'landmark.' If so, how is translocation specified in the geocentric and viewpoint-centered FoRs, in which there are (arguably) no landmarks? This requires the concept of direction, defined as a vector along one of the axes provided by a frame of reference (Example (12)):

(12a)	The plane is flying that way.	FoR: VIEWPOINT-C
(12b)	The plane is flying north.	FoR: GEOCENTRIC
(12c)	The plane is flying toward the North Pole.	FoR: OBJECT-C

When 'satellite-framed' languages (Talmy, 2000) that typically do not conflate path information into their motion verbs nevertheless seem to do so (e.g., *sink*, *fall*, *rise*), it can be shown that it is not path, but rather direction, that is being conflated (Zlatev, 2003).

Motion

Similar to the two ways of characterizing path, there is an imagistic and a minimal way of characterizing the concept of motion. The first would treat as motion not only expressions such as those in Examples (12a)–(12c), but also cases of so-called fictive motion (Talmy, 2000), as in Examples (13a)–(13f):

(13a)	The scenery rushed past us.	('Frame-relative motion')
(13b)	I looked toward the valley.	('Sensory path')
(13c)	The road goes through the woods.	('Coverage path')
(13d)	The church faces toward the square.	('Emanation path')
(13e)	The beam leans away from the wall.	('Advent path')
(13f)	His office is through the corridor.	('Access path')

The term following each example is from Talmy (2000), who presented an elaborate classification of types of fictive motion, claiming that motion exists at different levels of 'palpability' and that "every speaker experiences a sense of motion for *some* fictive motion constructions" (2000: I, 114). However, the classification is based very much on the author's private introspection, rather than on shared linguistic intuitions, and appears as a somewhat *ad hoc*. The alternative is to treat motion as a binary category: either the described scene involves perceived motion, and in that case we have translocation, or it does not, and the expression is one of location. This would make only Example (13a) translocative. At the same time, if motion is treated separately from the categories of path and direction, it is still possible to account for the 'fictive motion' aspect of, e.g.,

Examples (13a)–(13f), by specifying other than ZERO values: Path/Direction: END for Examples (13b) and (13d), Path: BEGINNING for Example (13e), and Path: MIDDLE for Examples (13c) and (13f).

Theoretical Controversies

Semantic or Conceptual

Three quite different standpoints have been adopted concerning the relation between spatial semantic meanings and language-independent conceptualization. The predominant view is that concepts such as path and (various values for) region constitute language-independent conceptual primitives (Talmy, 1983; Mandler, 1996). From this perspective, the function of language is simply to express (symbolize, lexicalize) conceptual representations such as image schemas (Johnson, 1987), which are largely of spatial nature and exist prior to and independently of language (Lakoff, 1987). Although Jackendoff's conceptual primitives differed in being 'digital' as opposed to 'analogue,' his semantic ontology was similar: "Conceptual structure . . . is an encoding of linguistic meaning that is independent of the particular language whose meaning it encodes" (Jackendoff, 1996: 5). In this theory, universal conceptual representations (CRs), defined by primitives such as PATH and PLACE, stand between an image-schematic spatial representation (SR) and linguistic forms (LFs).

Given the assumptions of either type of conceptual universalism, the only route for accounting for language-specific semantic differences is through choice of the underlying primitives and lexicalization patterns. However, there is more cross-linguistic variation than this approach predicts. For example, Korean lexicalizes the notions of TIGHT FIT and LOOSE FIT in a way that cuts across English INTERIOR and SUPPORT, and furthermore, these differences are acquired early by children (Bowerman, 1996). Even more problematic for a universal conceptual representation of spatial meaning are corroborations of linguistic relativity/mediation with respect to space, such as those shown with respect to frame of reference (Levinson, 2003).

The classic alternative is to view meaning as immanent in the usage patterns of the language. With respect to spatial meaning, this view has been defended by Bowerman (1996) on the grounds of extensive and developmentally early cross-linguistic variation. By distinguishing semantic and conceptual structure, however, Bowerman remained noncommitted on the question whether and to what degree these differences translate into conceptual differences. Indeed, still very much an open issue is to what extent linguistic differences of spatial meaning affect general cognition, and there are persistent findings that it is not a matter of complete determination (Gennari *et al.*, 2002).

The third possibility represents a synthesis of the preceding two, in stating that spatial semantic categories are based on prelinguistic experience, hence broad cross-linguistic similarities are expected, but language-specifically conventionalized, and hence there should also be differences. Regier's (1996) connectionist model can be seen as an explication of the idea of how a constrained, though flexible initial state can result in different spatial semantic systems, depending on the semantic structure of the language being acquired. From this perspective, semantic, perceptual, and conceptual structures are related but remain separate (Levinson, 1996). Categories of perception motivate categories of language, but do not determine them. Conversely, semantic structures may not affect, e.g., visual perception to any significant degree, but conceptual structures that are largely culturally mediated, such as spatial orientation, may be, more or less strongly, influenced by linguistic categories. The interactionist position appears to have the most support, but it should be mentioned that it is the least constrained of the three, and requires considerable methodological sophistication in order to be elaborated.

Localization or Distribution

As pointed out, the common answer is that spatial meaning is expressed by the members of one (or more) closed classes – e.g., Talmy (1983), Svorou (1994), and Regier (1996) acknowledged that sometimes open classes such as nouns and verbs participate in the expression, but insisted that the grammatical elements have priority. This, however, is objected to by Brown (1994), Sinha and Kuteva (1995), Ameka (1995), and Zlatev (1997, 2003), among others, on the basis of many examples from typologically different languages (e.g., Tzeltal, Ewe, Japanese, and Thai). As Sinha and Kuteva (1995: 168) argued, "an adequate analysis requires the abandonment of the localist approach, and the analysis of how spatial relational meaning is syntagmatically distributed over simultaneous selections from closed and open form classes."

Zlatev (1997, 2003) assumed representations such as that in Figure 3 which allows for a many-to-many mapping between semantic concepts and forms classes without privileging the closed classes. Conflation patterns (Talmy, 2000), distribution patterns (Sinha and Kuteva, 1995), and patterns of compositionality (Ameka, 1995) appear as special cases of such a mapping.

Figure 3 A representation of a form-meaning mapping involving conflation and distribution patterns, as well as pragmatic inferencing (the dashed line). Reprinted from Zlatev (1997), with permission.

Semantic or Pragmatic

In contradistinction to traditional analyses that attempt to separate conventional semantic meaning from contextual interpretation, cognitive linguists usually insist that (spatial) meaning is encyclopedic and that there is no non-arbitrary boundary between semantics and pragmatics (Langacker, 1987). This view would imply a 'full specification' account of the meaning of the prepositions in Examples (14) and (15), and would state that the expressions in Examples (14a) and (14b) involve different senses expressing different profiled regions:

(14a)	John flew *over* the bridge.	Region: SUPERIOR
(14b)	John walked *over* the bridge.	Region: SURFACE
(15a)	The room is *at the back of* the school.	Region: INTERIOR
(15b)	The tree is *at the back of* the school.	Region: EXTERIOR

An alternative analysis is to state that the prepositions do not express the relevant distinctions involving the category region semantically, but that the appropriate interpretation is derived through the gestalt-like properties of the expressed situation (see the dashed line in Figure 3) and the background of practices (Zlatev, 1997; Tyler and Evans, 2001), i.e., through pragmatic inferencing. Zlatev (2003) argued that a separation between semantics and pragmatics along these lines can provide the important cross-linguistic (typological) generalizations, and is therefore to be preferred.

The Nature of Spatial Polysemy

The ubiquitous polysemy of lexical meaning is commonly represented by analyses presenting networks of nodes standing for different senses connected via asymmetrical links. One of the most well-known applications for this kind of analysis has been precisely the semantics of spatial expressions, wherein non-spatial senses are (nearly) always treated as extensions from the spatial ones. Are such networks a characterization of psychologically real structures and/or processes and thus relate to the individual psychological level of language, or are they descriptive generalizations over the potential usages of the expressions in question? Sandra and Rice (1995) raised this question and critiqued the representational and methodological vagueness of network analyses, pointing out "the problem of determining whether the fine distinctions are part of the mental representation (as predicted by the prepositional network approach) or the result of an interaction between monosemous mental representations and a process of contextual supplementation" (1995: 125).

In a number of psycholinguistic studies summarized by Cuyckens *et al.* (1997), the evidence by and large does not support a direct mental representation of polysemous networks with spatial prototypes and metaphorical extensions. In brief, first-language acquisition studies do not show spatially 'transparent' uses to be regularly acquired before the more abstract and idiomatic ones. In sentence sorting and similarity judgment tasks, speakers do not regard polysemous spatial and non-spatial senses to be more closely related than homonymous (i.e., non-related) controls. Finally, and most crucially, primed lexical decision tasks show that spatial senses of the prepositions *at*, *on*, and *in* do not facilitate, but rather inhibit, the recognition of examples with temporal senses, attesting separate storage in memory. Although each one of these results can be multiply interpreted, taken together, they question both the existence of polysemy networks and the primacy of space on the psychological level. At the same time, this does not invalidate analyses of polysemy as explications of linguistic knowledge on the collective, conventional level (Itkonen, 1978). However, such analyses have to be made accountable to criteria of "descriptive economy, naturalness, generality and explanatory power" (Cuyckens *et al.*, 1997: 51) and above all – on intersubjective agreement – criteria that are often shunned within cognitivist approaches. A classic in the literature concerns the polysemy of *over* (Brugman, 1988), and it can illustrate how a spatial semantic analysis requires such criteria. Lakoff (1987) reformulated Brugman's analysis into an elaborate radial category

representation of 24 interrelated senses. His analysis has been criticized for lacking simplicity and rigor, since it attributed to usages such as those in Examples (15a) and (15b) the status of separate senses (Kreizer, 1997). Tyler and Evans (2001) argued for a systematic methodology of 'principled polysemy' and proposed a network of 13 distinct senses, derived diachronically through pragmatic inferencing and reanalysis from a single 'protoscene' in which the trajector is above but within the sphere of influence (and potential contact) with the landmark. Interestingly, the sense that Brugman (1988) and Lakoff (1987) assumed to be central, the 'over–across' sense of Example (16), does not even figure as a separate sense in the analysis of Tyler and Evans: it is rather explained as a contextual interpretation arising from the atemporal (i.e., static) meaning of the preposition, the dynamic meaning of the motion verb, and the knowledge of properties of walls and bridges:

(16a) The cat jumped over the wall.
(16b) He drove over the bridge.

Whether this analysis will be generally accepted is doubtful, but the major metatheoretical point of Tyler and Evans (2001: 733) on the need for a "methodology . . . that provides a rigorous and relatively consistent way of making judgments about whether a sense is distinct, and . . . can be used in an intersubjective way" should be uncontroversial.

Summary

Spatial semantics research is concerned with the definition of spatial semantics, the description of spatial semantic concepts, and the important theoretical controversies that any theory of spatial semantics would need to address. More theoretical work is needed in order to relate the conceptual and descriptive systems of different spatial semanticists, and to show where disagreements are only terminological and where they are substantial. In the latter case, a theoretical synthesis could be sought in an attempt to find a resolution of the persistent theoretical controversies.

The typological database of spatial analyses is being constantly extended with new languages, allowing better cross-linguistic generalizations. Furthermore, diachronic evidence, although not discussed here, is being taken into account to a greater degree, and it is possible that this will provide a more satisfactory explanation of patterns of polysemy and the 'primacy of space' than has been provided by synchronic psychological processes. Psycholinguistic studies have provided more questions than answers: Is there a principled way to distinguish polysemy from homonymy on the one hand, and from generality on the other? In which way does language mediate spatial thinking? The existing experimental paradigms need to be cross-checked for converging evidence, and new types of experiments are likely to be considered. Valuable new evidence for uncovering parallels between the linguistic and conceptual structure of space is likely to be found in gesture studies (Kita and Özyürek, 2003).

Finally, the existence of different ontological levels of linguistic meaning (i.e., the physical, the phenomenological, and the social), each with its appropriate methodology (Itkonen, 1978), is beginning to be more widely acknowledged, along with acknowledgment of a rehabilitation of the social-normative level of (spatial) meaning that is accessible through 'intersubjectively valid intuitions'. This is essential for any kind of consensus to be able to emerge within a field that has tended to oscillate between excessive private introspection and overemphasis on objective empirical data.

The linguistic literature contains a wealth of information about semantics, on the one hand, and fieldwork methodology, on the other, yet it devotes comparatively little attention to the combination of semantics and fieldwork. Although the semantics literature acknowledges potential difficulties when researchers collect and semantically analyze data in less-described languages, its focus is clearly on the well-studied European languages (and often on English alone). Conversely, although the fieldwork literature considers many different aspects of data collection and language description, the investigation of semantic phenomena is rarely discussed (with the notable exception of specific semantic fields, e.g., kinship terminology, as found in the literature on linguistic anthropology). As a result, many fieldwork-based studies contain little semantic information, and our knowledge of non-European semantics remains limited.

This lack of convergence is not accidental: Semantic analysis relies to a great extent on native-speaker intuitions about the acceptability and equivalence of expressions, but field linguists are generally not native speakers of the languages they analyze. That is, they cannot resort to their own intuitions in order to determine the meaning of an expression, to distinguish between ambiguity and vagueness, to establish sense relations, or to set apart semantic entailments from pragmatic implicatures. Instead, they have to infer the meaning of an expression from observing its use in context or from eliciting grammaticality and acceptability judgments. In the first case, they need access to a text corpus, which has to be as large and diversified as possible (because many expressions occur only infrequently or are restricted to specific genres). In the second case, they need access to a thorough grammatical description (to be able to construct appropriate contexts and test sentences). However, neither corpora nor grammatical descriptions are usually available for the less-described languages. In most cases, such materials have to be created in a painstaking and time-consuming way by the field linguists

Semantics: Field Work Methods

B Hellwig, School of Oriental and African Studies, London, UK

© 2006 Elsevier Ltd. All rights reserved.

The linguistic literature contains a wealth of information about semantics, on the one hand, and fieldwork methodology, on the other, yet it devotes comparatively little attention to the combination of semantics and fieldwork. Although the semantics literature acknowledges potential difficulties when researchers collect and semantically analyze data in less-described languages, its focus is clearly on the well-studied European languages (and often on English alone). Conversely, although the fieldwork literature considers many different aspects of data collection and language description, the investigation of semantic phenomena is rarely discussed (with the notable exception of specific semantic fields, e.g., kinship terminology, as found in the literature on linguistic anthropology). As a result, many fieldwork-based studies contain little semantic information, and our knowledge of non-European semantics remains limited.

This lack of convergence is not accidental: Semantic analysis relies to a great extent on native-speaker intuitions about the acceptability and equivalence of expressions, but field linguists are generally not native speakers of the languages they analyze. That is, they cannot resort to their own intuitions in order to determine the meaning of an expression, to distinguish between ambiguity and vagueness, to establish sense relations, or to set apart semantic entailments from pragmatic implicatures. Instead, they have to infer the meaning of an expression from observing its use in context or from eliciting grammaticality and acceptability judgments. In the first case, they need access to a text corpus, which has to be as large and diversified as possible (because many expressions occur only infrequently or are restricted to specific genres). In the second case, they need access to a thorough grammatical description (to be able to construct appropriate contexts and test sentences). However, neither corpora nor grammatical descriptions are usually available for the less-described languages. In most cases, such materials have to be created in a painstaking and time-consuming way by the field linguists

themselves before they can embark on a semantic investigation.

Field linguists thus face two major challenges: the lack of suitable data and the problems of conducting an intensional semantic analysis on the basis of observed and elicited extensional data. In recent years, a number of studies have appeared that (explicitly or implicitly) address these methodological issues. These impulses come especially from the fields of semantic typology (aiming at a semantic comparison of languages and, therefore, needing comparable semantic data), documentary linguistics and linguistic anthropology (aiming at an adequate description and documentation of all areas of language, including semantics), cognitive linguistics (aiming at investigating possible cognitive correlates of linguistic phenomena), and language acquisition (aiming at understanding the learner's developing knowledge of the semantic structure of the target language).

Depending on the research question and the requirements of a particular field site, these studies exemplify quite a variety of fieldwork techniques: They ask speakers to describe objects, pictures, or video clips; to retell picture book or video stories; to play games; to respond to reenacted scenes from questionnaires or to (nonlinguistic) triads and categorization tasks; or – as in the probably best-known studies – they use color charts to discuss color terminology. Despite this attested variety, all studies propose to address the methodological issues in similar ways: They create controlled contexts that can generate a large number of desired target expressions, and, in particular, they use (visual) stimuli to create these contexts. By way of an example, two such stimuli are illustrated here: picture elicitation and matching games (see the bibliography at the end of this article for other examples).

In picture elicitation, speakers are presented with pictures and are then asked a question that would conceivably generate the target expression. **Figure 1** is an example of such a stimuli picture (designed to elicit locative expressions) and example (1) illustrates the prompt by the field linguist and the subsequent discussion between a linguist and speaker (conducted in the West Chadic language Goemai).

(1) Linguist: *Kwalba hok d'e nnang* ?
'Where is the bottle?'
Speaker: *T'ong k'a tebul.*
'It sits on the table.'
Linguist: *Ko d'yem k'a tebul a* ?
'Or does it stand on the table?'
Speaker: *A'a, d'yem ba, goe sh'e ba.*
'No, it doesn't stand, (because) it doesn't have a leg.'

Figure 1 Picture elicitation: Stimuli picture discussed in example (1).

In matching games, two speakers interact with on another, one speaker assuming the role of 'director' and the other the role of 'matcher.' In many studies, the two players are screened off from one another and are given a set of identical pictures. The director is asked to pick one of the pictures and to describe it to the matcher, who then picks the corresponding picture from his or her set. Because the two players cannot see one another, they have to rely on verbal descriptions for this purpose. After having identified a picture, both players put their chosen picture aside on a pile, and the director picks another one from the set. In the end, the screen is removed, and the players compare their piles to check if they match. **Figure 2A and B** present two of the stimuli pictures (out of a set of 16 pictures), and example (2) illustrates such a matching game and the resulting discussion between the two players (who, again, speak the West Chadic language Goemai).

(2) Director: *Ndoe kwalba na nd'e. D'yem k'a tebul.*
'See a bottle here. It stands on the table.'
The Director describes the upright bottle (**Figure 2A**), but matcher picks the upside-down one (**Figure 2B**). At the end of the game, they compare their piles (pointing at the different pictures).
Director: *A'a, d'yem k'a tebul muk mu?*
'No (= not **Figure 2B**), it (= **Figure 2A**) stands on its table, right?'
Matcher: *Ai, t'ong, moe yi: t'ong k'a tebul, ai. Nd'yem ba ai.*
'Hey, it (= **Figure 2A**) sits, we say: it sits on the table, hey. Not standing, hey.'

In this way, stimuli-based setups generate a large amount of data about the use of target expressions in reference to real world contexts; that is, they generate

Figure 2 Matching games: Stimuli pictures discussed in example (2).

extensional data. At the same time, they also generate relevant information that makes the collected data accessible to an intensional analysis. Such an analysis is facilitated by the following characteristics of stimuli-based methods:

- The researcher exercises some control over the setup, allowing him or her to either probe for parameters that potentially determine the use of an expression or to systematically test hypotheses.
- The context and tested parameters are held constant; that is, the same task can be run with different speakers for purposes of comparison. Such data lend themselves to a quantification of preferred expressions or of dialectal and crosslinguistic variation.
- The setups provide speakers with a clear reference context for their answers, thereby reducing the risks of generating translation equivalents and misunderstandings. It is known that speakers tend to judge the acceptability of an expression against a specific context. If the researcher can provide such a context, the speakers can use it – otherwise, they have to create it themselves outside the control of the researcher, introducing potential misunderstandings. Furthermore, knowledge about the reference context makes it possible for the researcher to take it into account in the process of analysis, that is, to relate expressions to real-world contexts, to recognize contextual factors that trigger particular usage patterns, or to discover stimuli effects.
- Many setups generate negative evidence (e.g., speakers and players explicitly judge certain expressions as inappropriate) as well as information about the equivalence of expressions (e.g., expressions by fellow players cause misunderstandings, and players negotiate and discuss alternative possibilities and contexts). And because many setups are not overtly concerned with the speech of the speakers (but, e.g., with finding the matching picture), they reduce the risk of prescriptive language use.

Such information is needed for any kind of semantic analysis, independent of the theoretical framework adopted and independent of whether the analyst is a native speaker of the language analyzed. In fact, there are more and more studies in which native-speaker linguists do not rely on their intuitions alone but exploit the advantages offered by employing stimuli-based methods.

However, it is also acknowledged that such methods have potential drawbacks: a cultural bias (because such setups are not always appropriate in all cultures and all circumstances) and a creation of stimuli effects and 'nonnaturalistic' language use (because speakers are asked to make fine-grained distinctions that they would not necessarily make in everyday life). Although such problems cannot be avoided, the literature agrees that they can be counterbalanced by diversifying the database. That is, two opposing criteria need to be balanced: the amount of control researchers can exercise over the context and the degree to which speakers can talk naturally. Because no set of data can satisfy both criteria equally well, it is advocated that different stimuli-based techniques be combined with one another and augmented with data from natural settings, from staged communicative events (i.e., linguistic events that are prompted by the researchers but in which speakers structure their texts freely; e.g., a speaker is asked to talk about the manufacture of baskets), and from elicitation sessions in which researchers elicit expressions, grammatical information, and so on. Taken together, these methods generate a broad spectrum of relevant data that can serve as the basis for a detailed semantic analysis.

The Philosophical Debate

Texts in the philosophy of language frequently cite the tripartite distinction between syntax, semantics, and pragmatics made by Morris (1938). According to Morris, syntax is concerned with the structural properties of signs (i.e., with word-word relations), semantics with the relations between signs and the things they signify (i.e., with word-world relations), and pragmatics with the uses of signs by speakers and hearers to perform communicative acts (i.e., with word-user relations).

Philosophers generally follow Frege in rejecting any form of mentalist semantics. They think of languages as "abstract semantic systems whereby symbols are associated with aspects of the world" (Lewis, 1972: 170). There is a potential infinity of both syntactically well-formed (grammatical) and semantically well-formed (meaningful) sentences in any language, and it is the job of semantics to identify rules that generate this potential infinity. On the other hand, since we are interested in the semantics of

Semantics–Pragmatics Boundary

The Philosophical Debate

Texts in the philosophy of language frequently cite the tripartite distinction between syntax, semantics, and pragmatics made by Morris (1938). According to Morris, syntax is concerned with the structural properties of signs (i.e., with word-word relations), semantics with the relations between signs and the things they signify (i.e., with word-world relations), and pragmatics with the uses of signs by speakers and hearers to perform communicative acts (i.e., with word-user relations).

Philosophers generally follow Frege in rejecting any form of mentalist semantics. They think of languages as "abstract semantic systems whereby symbols are associated with aspects of the world" (Lewis, 1972: 170). There is a potential infinity of both syntactically well-formed (grammatical) and semantically well-formed (meaningful) sentences in any language, and it is the job of semantics to identify rules that generate this potential infinity. On the other hand, since we are interested in the semantics of

natural languages, these rules must be ones that are learnable by humans with finite minds. Semanticists are interested in what a competent speaker knows when she knows a language (i.e., her syntactic and semantic competence). Hence they assume that what a speaker knows is a **finite** set of rules that can compositionally generate the potential infinity of syntactically well-formed sentences and that can deliver a **semantic interpretation** for every meaningful sentence of the language.

Philosophers generally assume that there is a sharp division between syntax/semantics and pragmatics. While semantics studies the rules that a competent speaker knows when she knows the meanings of sentences, pragmatics studies how sentences are used in conversational contexts to communicate a speaker's messages. Pragmatics is thus concerned with linguistic **performance** rather than competence. It is **by** using sentences with certain syntactic and semantic properties that speakers succeed in communicating certain things. So, the central question of pragmatics is how we succeed in our communicative tasks.

Many philosophers are convinced that Grice (1975, 1989) made an important start in answering this question by articulating his Cooperative Principle and maxims of conversation. Grice sees conversations as rational cooperative activities where hearers use their linguistic knowledge, together with mutually available nonlinguistic contextual knowledge, to infer what the speaker means to communicate. The principles that guide conversations are analogous to the principles that guide any sort of rational cooperative activity, such as the joint activity of building a house or sailing a ship. Pragmatic principles on this view are not tied essentially to any language mechanism and are certainly not language-specific rules, unlike the syntactic and semantic rules that define a language.

An alternative view, argued for by Prince (1988, 1997), assumes that there are rules of use associating certain linguistic forms with certain functions. Moreover, these rules are language-specific, in the sense that the same pragmatic function could be served in different languages by different forms; so any competent speaker of the language must learn these rules. Knowledge of these rules constitutes the speaker's pragmatic competence. Hence it is incorrect to put the study of pragmatics on the performance side of the competence/performance divide. Related to Prince's ideas are those of Kasher (1991), who argues for a modular conception of pragmatics. Just as linguists have postulated a grammar module, so Kasher argues there is a module governing pragmatic processes, with its own proprietary rules and representations. Since it is Grice's conception of pragmatics that has set the agenda for debate in the philosophy of language, these alternative views will be set aside here.

Gricean pragmatics introduces the idea that it is **by** saying certain things in certain contexts that speakers are able indirectly to communicate (to implicate) certain further things. In working out what a speaker has implicated, a hearer will use his knowledge of the conversational maxims, together with contextually available knowledge, to infer what the speaker communicated. For example, after a terrible ordeal in which a man is rescued from a remote mountainside after a plane crash, a TV reporter interviews him. The reporter asks: 'Were you ever afraid?' and the man replies: 'I felt a twinge or two.' By his understatement he has implicated that things were pretty bad. The understatement is a violation of Grice's first Maxim of Quantity, which enjoins speakers to say as much as is required by the purposes of the talk exchange. The hearer, having recognized the violation, but assuming that the speaker is still bound by the Cooperative Principle, will search the context for further information that the speaker might have intended to convey. It is his background knowledge – of human psychology, of the probable consequences of plane wrecks, and of the low probability of survivors being found in remote, sparsely populated places – that allows the reporter to infer the speaker's intended meaning.

The currently dominant view in philosophy of language is that a theory of meaning for a language specifies the truth-conditions for each of the sentences of a language. It does this by specifying a finite set of rules that compositionally generates these truth-conditions. This truth-conditional approach to semantics has been grafted onto a Gricean view of pragmatics. It is generally accepted that saying and implicating are neatly separated. Saying is tied to sentence meaning and the expression of truth-conditional content. What a speaker says when she utters a sentence (i.e., the locutionary content of her utterance) corresponds to the truth-conditional content of the sentence. (Note that the notion of **saying** is not to be conflated with the notion of **stating**. The former is a locutionary act, namely the act of expressing some content. The latter is an illocutionary act. It is the expressing of some content with a particular illocutionary force.) Implicating is tied to (indirectly or implicitly) communicated content that can be inferred once the hearer has figured out what the speaker has (directly or explicitly) said. Since truth-conditional content is the province of semantics and implicature is the province of pragmatics, the saying/implicating divide goes along with a neat divide between semantics and pragmatics. Consequently, many believe that truth-conditions can be specified in a way that is essentially free from pragmatic considerations.

But there are problems with this Gricean view. One of the first indications of trouble for this view came from some observations by Cohen (1971). Others, such as Carston (1988, 2002), Levinson (1995, 2000) and Recanati (1989, 2004) have used examples similar to Cohen's to challenge the Gricean picture. Consider examples such as the following:

(1) Mary fell pregnant and she got married.
(2) Mary got married and she fell pregnant.

Grice would say that (1) and (2) have the same truth-conditional content, but that they implicate different things. (1) implicates (in a generalized way) that the pregnancy occurred before the marriage, whereas (2) implicates the opposite. (1) also implicates that the reason for Mary's marriage was her pregnancy. However consider examples such as the following:

(3) If Mary fell pregnant and she got married, her grandma will be shocked.
(4) If Mary got married and she fell pregnant, her grandma will be shocked.

According to Grice, the antecedents of the two conditionals have the same truth-conditional content. Therefore, (3) and (4) should themselves have the same truth-conditional content, yet intuitively they do not. (3) could be true while (4) is false. It looks as though the implicated content of (1) and (2) has become incorporated into the truth-conditional content of (3) and (4). In other words, (3) and (4) in effect express the following:

(3′) If Mary fell pregnant *and then for that reason* she got married, her grandma will be shocked.
(4′) If Mary got married *and then* she fell pregnant, her grandma will be shocked.

Clearly, (3′) and (4′) differ in content, so it is not a problem if one is true and the other is false.

These appear to be cases of pragmatic intrusion into truth-conditional content. Such pragmatic intrusion creates a problem for Grice that Levinson (2000) calls 'Grice's Circle.' The trouble is that to figure out what is conversationally implicated, the hearer must first determine what is said (since it is **by** saying such-and-such that a speaker succeeds in implicating something else). However, in figuring out what was said by (3) or (4), it looks as though one must first determine their implicated contents.

Levinson (1995, 2000) argues that pragmatic intrusion is not problematic, since it is limited to the intrusion of **generalized** conversational implicatures (GCIs), and these, he argues, are **default meanings** that will be automatically triggered by the use of certain kinds of expressions. The derivation of GCIs is governed by various heuristic principles. For example, the I-Principle can be summarized in the slogan 'What is simply described is stereotypically and specifically exemplified.' It applies only to 'unmarked, minimal expressions' (Levinson, 1995: 97). It enjoins speakers to minimize what they say when their hearers are able to use contextually accessible information to enrich the informational content of their utterances. Conversely, it enjoins hearers to amplify or enrich the informational content of the speaker's utterance up to the point that they judge is the speaker's intended meaning. Since 'and' is the sort of minimal, unmarked expression that calls for a stereotypical interpretation, conjunctions such as (1) and (2) will be given an interpretation according to which the events described by the two conjuncts are temporally ordered. The net effect is that (3) and (4) will be understood to express (3′) and (4′) respectively.

Not everyone would agree that in (3) and (4) we have pragmatic intrusion into truth-conditional content. Cohen (1971) appeals to examples of embedded conjunctions that seem to affect the truth-conditions of the larger sentences in which they are embedded to argue for a **semantic ambiguity** account of 'and.' If the suggestion of temporal ordering associated with (1) affects the truth-conditions of (3), Cohen concludes that this feature must be part of the semantically encoded meaning of 'and.' Since relations other than temporal ordering can be suggested by a conjunction, this view is committed to a multiple ambiguity account of 'and.' In addition to conjunctions such as (1) and (2), consider examples such as:

(5) It is summer in Europe and winter in Australia.
(6) The fan turned on and {as a result} a cool breeze blew through the room.
(7) Peter took a shower and {while in the shower} he practiced his singing.

In some cases, as in example (5), 'and' expresses simple truth-functional 'and,' and the conjuncts can be reversed without changing the meaning. In others, such as (6), it expresses a causal relation 'and as a result,' or, as in (7), a temporal containment relation 'and while.' In these last two cases, the relations are asymmetric, and reversing the conjuncts changes the meaning. For instance, reversing (6) suggests a different causal scenario, where the breeze somehow turns on the fan. Examples could be multiplied, and for each case where a different relation is suggested, Cohen would have to posit yet another meaning for 'and.'

Carston (1988) and Recanati (1989) argue against positing a semantic ambiguity for 'and,' maintaining instead that the contents represented between

brackets in the above examples are **pragmatically determined aspects of what is said**. (See entry on **Pragmatic Determinants of What Is Said**.) Rather than being semantically ambiguous, 'and' is **semantically underspecified**. It will be pragmatically enriched in different ways, depending on the assumptions that are operative in the conversational context.

Carston and Recanati agree with Levinson that there is pragmatic intrusion. However, they point to embedded contexts, like the conditionals (3) and (4), to argue that the pragmatic content associated with (1) and (2) belongs to what is said, rather than being conversationally implicated. (Carston (2002) prefers to use Sperber and Wilson's (1986) technical term 'explicature' instead of the term 'what is said,' since the latter has a commonsense usage that interferes with attempts at terminological regimentation.) If the pragmatic content of a simple sentence has an effect on the truth-conditional content of the compound sentences in which it is embedded, then that pragmatic content is part of what is said by the simple sentence, not something that is merely implicated. Recanati calls this the Scope Test.

Other tests have been proposed for determining whether some pragmatically determined content is part of what is said. Recanati (1989) proposes his Availability Principle, according to which any content that intuitively seems to affect truth-conditions should be regarded as a part of what is said. Carston (1988) proposes her Functional Independence Principle, which requires both explicatures and implicatures to occupy independent roles in inferential interactions with other assumptions. Take example (8) discussed below. The simple encoded content that Mary engaged in an act of swallowing is not functionally independent of the enriched content that Mary swallowed a bug. The latter entails the former, and it is from the latter that further contextual effects can be derived. This suggests that it is the enriched content that corresponds to what is said, not the more minimal encoded content, which has no autonomous role to play.

Explicatures are pragmatic developments of semantically encoded content and can be either **enrichments** or **loosenings** of encoded content. Carston argues that the processes involved in the recovery of explicatures are inferential processes and, hence, no different from the sorts of inferential processes involved in the derivation of conversational implicatures. What distinguish explicatures from implicatures are not the sorts of processes involved in their derivation but the starting points of these inferential processes. Derivations of explicatures begin with the semantically underspecified representations of logical form (LF) that are the output of processes of grammatical decoding. Implicatures, on the other hand, as Grice insisted, are contextual implications that follow from contexts including assumptions about what was said (i.e., including explicatures). This is **not** a commitment to the claim that explicatures are processed before implicatures. In fact, Carston thinks that the processing of explicatures and implicatures happens in parallel, and that the overall interpretation of a speaker's utterance is something arrived at via a process of mutual adjustment.

Recanati, on the other hand, distinguishes local from global pragmatic processes. The sorts of processes involved in the derivation of pragmatic determinants of what is said are of the local sort and are noninferential. For instance, such local processes might involve spreading activation within an associative conceptual network, or the accessing of stereotypical information from conceptual frames or scripts. Such processing happens at a subconscious level, and only the output of such processes is consciously available. In contrast, global pragmatic processes are inferential processes of the sort that Grice claimed are involved in the derivation of conversational implicatures. Such inferential processing is in principle consciously available, in the sense that language users can become aware not just of the conclusions of such reasoning but also of the inputs to such reasoning, as well as to the (putative) fact that premises and conclusions are inferentially connected.

Bach (1994) provides yet another perspective on these matters. Bach wishes to maintain a more minimalist conception of semantics and of what is said. Yet he acknowledges that there are pragmatically determined contents that are not Gricean implicatures. He introduces a third category of contents, intermediate between what is said and what is implicated, that he labels 'implicitures.' He regards these as contents that are implicit in what is said and that require pragmatic processes of either **completion** or **expansion** to be made explicit. Consider the following, where the content in brackets is supplied from contextually available information:

(8) Mary swallowed {the bug that flew into her mouth}.

(9) Mary invited everyone {in her department} to her wedding.

The sentence 'Mary swallowed' is syntactically and semantically complete. (Compare it to 'Mary ate,' which is syntactically but not semantically complete, since 'eat' is a two-place relation. Or to 'Mary devoured,' which is neither syntactically nor semantically complete, since 'to devour' subcategorizes for an obligatory second NP, and 'devour' has two semantic arguments). Bach regards (8) as an example of

conceptual incompleteness, and hence a pragmatic process of completion must operate, resulting in the derivation of the impliciture that Mary swallowed the bug that flew into her mouth.

On the other hand, 'Mary invited everyone to her wedding' expresses a complete proposition. Bach calls this a **minimal proposition**, since the domain of the quantifier is not restricted in any way (beyond the restriction to persons that is encoded by 'one' in 'everyone'). However, this minimal proposition is not the one that the speaker intends to communicate. A pragmatic process of expansion is required, yielding the impliciture that Mary invited everyone in her department to her wedding. Bach calls examples such as (9) cases of **sentence nonliterality**. No expression in the sentence is used nonliterally, yet the minimal proposition expressed by the sentence is not what the speaker intends to convey.

Bach denies that there are pragmatically determined aspects of what is said. What is said for Bach is a more minimal notion, which is tied to explicitly encoded semantic content. Bach in effect accepts what Carston (1988) calls the Linguistic Direction Principle. The only contextually determined content that belongs to what is said by the utterance of a sentence is content that corresponds to some element that is syntactically realized in that sentence. Thus the contextual values of the indexicals in 'She is swallowing now' will be part of what is said by an utterance of this sentence, but the implicit content that specifies what was swallowed (if anything) will not be a part of what is said, since that content corresponds to no element in the sentence. Bach's minimalism requires him to admit that on some occasions what a speaker says does not correspond to a complete proposition. Such is the case in example (8) above. In such cases Bach argues that what is said corresponds to a 'propositional radical,' a gappy object whose missing conceptual elements must be supplied by the context.

Each of the authors discussed above posits a different view of the boundary between semantics and pragmatics. According to Grice, sentence meaning, truth-conditional content, and what is said are all aligned and fall on the side of semantics, whereas implicatures fall on the side of pragmatics. Cohen basically preserves Grice's dichotomy. Cases that may seem to be pragmatic intrusions into truth-conditional content are instead incorporated into semantics. If there is a challenge to Grice it is simply that some phenomena that Grice would label as conversational implicatures are reanalyzed by Cohen as part of semantically encoded content, so that the domain of pragmatics shrinks.

Subsequent views can all in one way or another be seen to challenge Grice's neat dichotomy. Bach remains the most faithful to Grice, since on the whole he preserves the alignment of sentence meaning, truth-conditional content, and what is said on the side of semantics. Truth-conditional content may sometimes come apart from what is said, in those cases in which what is said is conceptually incomplete and hence does not correspond to a complete, truth-evaluable proposition. But when we have truth-conditional content, it is something that is delivered purely by semantics. However, Bach argues that Grice's view of what lies on the side of pragmatics is inadequate. The phenomena of semantic underspecification and sentence nonliterality require us to recognize a category of pragmatic content intermediate between what is said and what is implicated – the category of implicitures.

Levinson's (1995, 2000) views are also quite close to Grice's. He accepts that sentence meaning and what is said line up, and that these are semantic phenomena. However, he allows that there can be pragmatic intrusion into truth-conditional content, so this notion is not a purely semantic notion. On the other hand, Levinson's conception of pragmatics is conservative. He does not challenge the adequacy of the Gricean conception of pragmatics as the domain of conversational implicatures. He does, however, develop Grice's notion of a generalized conversational implicature (GCI) to a substantial degree. GCIs are said to be default meanings, which belong to a third level of meaning that Levinson calls utterance-level meaning, different from either sentence meaning or speaker meaning. It is only GCIs that are involved in pragmatic intrusion.

Carston's and Recanati's challenges to Grice are more radical. For them, the only purely semantic notion is sentence or expression meaning. What is said (which is equated with truth-conditional content) falls on the side of pragmatics, since there is pragmatic intrusion into truth-conditional content. (Remember, Carston prefers the term 'explicature.') Carston (2002) suggests that we make a distinction between lexical and truth-conditional semantics. Lexical semantics studies those aspects of meaning that have some sort of syntactic reflex in the language and hence that are a part of the mental lexicon. The lexicon is a store of words in long-term memory. An entry in the mental lexicon is in effect a rule correlating the phonological, syntactic, and semantic information associated with a word. Lexical semantics on this conception is a mentalist enterprise. We can continue to talk of truth-conditional semantics, so long as we realize that the project is very different from the traditional one. Truth-conditions are not assigned directly to the sentences of a language, since sentences by themselves do not have truth-conditions. It is

only sentences as used by speakers in particular conversational contexts that have truth-conditions. For a defense of a similar claim, see Stainton (2000).

Moreover, both Carston and Recanati reject Gricean pragmatics as inadequate, since for them pragmatics is not confined to the study of conversational implicatures. Recanati's rejection of Gricean pragmatics may be the most thoroughgoing, since for him, the pragmatic processes involved in the recovery of what is said are not even of the same type as the global pragmatic processes involved in the recovery of implicatures. They are noninferential processes.

Many other voices have been added to this debate. For example, Stainton (1995) argues for the view that semantic underspecification and pragmatic intrusion is rife. He points to the fact that many utterances are of sentence fragments, rather than of complete sentences. Consider:

(10) Top shelf.

Suppose Mary is making herself a sandwich and is rooting around in the kitchen cupboard looking for jam to spread on her toast, and that this is mutually manifest to Mary and her husband Peter. Peter could utter sentence fragment (10), meaning to convey the proposition that the jam that Mary is looking for is on the top shelf of the cupboard she is searching in. Stainton argues that cases such as these are not to be treated as cases of ellipsis. The missing content in (10) need not correspond to any well-defined syntactic element, as happens in standard cases of syntactic ellipsis, such as the VP-ellipsis in 'Mary donated blood and so did Peter.' (Ellipsis is a very vexed subject. Whether it is something that can be handled in the syntax is not at all clear. See Jackendoff, 1997: 75–78, for a discussion of some problematic cases.) We should accept that language understanding is able to proceed on the basis of fragmentary clues from semantically decoded content. A large burden is placed on the inferential capacities of hearers, who must elaborate these clues on the basis of contextually available information.

Stanley (2002) argues for a diametrically opposed view. According to Stanley, there is much more syntactic and semantic structure than meets the eye, and many of the alleged cases of semantic underdetermination calling for pragmatic enrichment can be reanalyzed as cases where some hidden element in the underlying sentential structure is directing the process of content retrieval. In other words, we preserve the idea of the linguistic direction of content, although the elements doing the directing are often hidden elements (ones that are not phonetically realized, although they are a part of underlying logical form).

Stanley's views have been especially influential in accounting for cases of quantifier domain restriction, such as (9) above or (11) below:

(11) Every child has been vaccinated against polio.

(12) In every country, every child has been vaccinated against polio.

It is possible to use (11) in an appropriate context to convey the proposition that every child **in the United States** has been vaccinated against polio. Stanley's view is that there must be a hidden free variable in (11) whose value is specified in that context as the United States. This variable is present in the underlying logical form of (11) but is not phonetically realized. (Strictly speaking, what is implicit is a free **function** variable, and what must be specified in context is both the function and the values of the arguments of this function. In (11) the function is something like 'resident-in(x).') The evidence that there is a hidden free variable in (11) is that this variable can sometimes be bound by a quantifier. For example, when (11) is embedded in a sentence with a quantifier that has wide scope over the embedded quantifier, as is the case in (12), what is said is that in every country *x*, every child *in x* has been vaccinated. For more detailed arguments, both pro and con, see Stanley and Szabó (2000), Bach (2000) and Neale (2000). This hidden indexical view has consequences for the quantificational analysis of definite descriptions and has led to some controversy as to the correct analysis of so-called incomplete descriptions. See the chapters in Part I of Reimer & Bezuidenhout (2004).

The Mentalist Picture of the Semantics-Pragmatics Boundary

It was noted above that many philosophers follow Frege in rejecting mentalist semantics. Many linguists on the other hand embrace mentalism, and in fact regard it as the only sensible perspective from which to study language. See Chomsky (2000), Jackendoff (1997, 2002). From the point of view of mentalism, the dispute about the semantics-pragmatics boundary is not one about how to delineate the notions of explicature, impliciture, implicature, etc. Rather, it is concerned with the question as to how semantic and pragmatic knowledge are represented and organized in the human mind/brain and how this information is combined in the course of on-line production and comprehension of language. Several of the authors discussed above straddle the divide between philosophy and linguistics. Carston, for instance, works in the mentalist tradition. She is concerned to offer a mentalist theory of language **performance**. (So the

suggestion made at the outset that semantics is concerned with competence and pragmatics with performance is one that Carston would reject.) On the other hand, although she is interested in articulating a cognitive theory of performance, she has also been an active contributor to the philosophical debate about how to delineate what is said from what is conversationally implied.

Within the mentalist framework, the dominant picture of the semantics-pragmatics interface has been that it is the interface between the language system proper and what Chomsky (1995) calls the conceptual-intentional system. From the comprehension perspective, this interface is where the output from the hearer's language system, namely a representation of the logical form (LF) of the speaker's utterance, is interpreted by processing it in the context of currently active pragmatic information, including information about the speaker's likely communicative intentions. From the production perspective, this interface is where the process of giving expression to a speaker's communicative intentions is initiated. Appropriate lexical-conceptual entries in the speaker's mental lexicon are accessed, thus initiating a process that will ultimately result in the output of an appropriate phonetic form (PF) at the interface between the language system and the articulatory system.

Jackendoff (1997, 2002) challenges this Chomskyan view while remaining within the mentalist camp. He argues that the language system has a tripartite parallel architecture. There are three independent generative systems or modules, the phonological system, the syntactic system, and the conceptual system. Each contains its own compositional rules and proprietary set of representations, of, respectively, phonological structure (PS), syntactic structure (SS), and conceptual structure (CS). However, it is necessary for these systems to communicate with one another, and they do this via various interface modules, whose job it is to map representations from one system into the representations of another. There is a PS-SS interface, an SS-CS interface (which Jackendoff calls the syntax-semantics interface), and a PS-CS interface. The lexicon is also an interface module, and the interfaces already mentioned are in effect parts of this larger interface system. The lexicon is a long-term memory store whose entries are triples of the three sorts of structures mentioned, namely of PS, SS, and CS. The lexical entry for expression α, $<PS_\alpha,SS_\alpha,CS_\alpha>$, is in essence a correspondence rule mapping representations from the three systems into each other. (Lexical entries may be for words, for phrases, such as idioms, or for expressions below the word level, such as agreement markers.)

What Jackendoff calls the syntax-semantics interface (namely the SS-CS interface) is of relevance to the current discussion, since he justifies his claim that CS is the level of semantics, and that it is a level separate from syntax, by appeal to phenomena of the sort that Carston, Recanati, and others appeal to in arguing for pragmatic intrusion into what is said (i.e., into the proposition expressed by an utterance). Jackendoff (1997) argues for what he calls enriched semantic composition. At the level of CS, the compositional principles that form propositions (or thoughts) are sensitive to information that comes from the pragmatic context. But not all this conceptual structure is reflected in the corresponding syntactic structures. Consider the following:

(13) Peter kept crossing the street.
(14) Mary finished the book.
(15) The ham sandwich wants his check.

(13) illustrates the process of aspectual coercion, (14) of co-composition, and (15) of pragmatic transfer. See Pustejovsky (1995) for an account of the first two processes and Nunberg (1979) for an account of the third.

A single act of crossing the street is not a repetitive and (potentially) open-ended action like clapping one's hands or bouncing or spinning a ball. But 'kept' requires such repetitiveness and/or open-endedness. Thus, in the case of (13), 'kept' coerces an interpretation of 'crossing the street' according to which there is either a repeated or an extended action. That is, either we understand Peter to have crossed the street multiple times, perhaps in his effort to lose the detective tailing him. Alternatively, we zoom in on Peter's action of crossing the street and see it as one whose end point is still in Peter's future. Perhaps the street is a very broad one, with a median strip, where Peter pauses briefly before continuing with his crossing.

In the case of (14), finishing is something that can be predicated of an event, but 'the book' refers to an object, not an event. Pustejovsky (1995) argues that the lexical-conceptual entry for 'book' contains information about the typical features of books, namely that they have authors, are read by readers, etc. This conceptual information, presumably along with other contextual information, can be used to arrive at an enriched interpretation of (14) according to which Mary finished reading (or writing, or binding, or illustrating, etc.) the book. In the case of (15), contextual knowledge about restaurants and what goes on in them is used to arrive at an interpretation according to which the ham sandwich orderer wants his check.

In all these cases Jackendoff argues that there is more conceptual (semantic) structure than is

represented syntactically. Some will be inclined to argue that there must be covert syntactic structure to match the semantic structure – structure that is there but is not phonetically realized. But Jackendoff argues that this is a mistake. Those who argue for covert structure are in the grip of an assumption that he calls syntactocentricism, namely the view that the only source of compositional structure is syntax. This is an assumption he attributes to Chomsky, since it is built into all the theories of the organization of the language system that Chomsky has proposed, from the Standard Theory of the 1960s, through the extended and revised versions of the Standard Theory in the 1970s, to the Government and Binding (GB) approach of the early 1980s and the minimalist approach of the 1990s. But Jackendoff's account of the tripartite parallel architecture of the language system rejects this assumption.

Moreover, Jackendoff goes further and argues that it is a mistake to talk of **any** semantic structure being directly encoded in the syntax, as Chomsky seems to suggest when he introduces the level of logical form (LF) and talks of it as the level in syntax that directly represents meaning (Chomsky, 1986: 68). It is unnecessary and perhaps even incoherent to talk in this way. First, it is unnecessary, since the correspondence rules belonging to the syntax-semantics interface (the SS-CS interface) will do the work of correlating syntactic and semantic structures. Note also that the correspondence doesn't have to be perfect. There may be only a partial homology between these two systems. If the communicative system as a whole works in such a way that semantic structure is recoverable from readily available contextual knowledge, then the fact that some of this structure is invisible to the syntactic system is no bad thing.

Second, talk of semantic structure being encoded in syntax may be incoherent if that is allowed to mean that semantic distinctions are directly represented in the syntactic system. The syntactic system is a module whose internal operations are defined over representations in its own proprietary code. So the syntactic system knows about nouns and verbs, case markings, active and passive constructions, WH-movement, etc., not about objects and events, predicate-argument structure, the telic/atelic distinction, thematic roles, etc. Thus it could not represent the sort of pragmatic knowledge needed to interpret examples such as (13)–(15).

As already mentioned, Carston accepts Chomsky's picture, including the assumption of syntactocentricism. She holds that the output from the language system is a representation of LF, which includes those semantic features that are directly syntactically encoded. Earlier we saw her acceptance of the idea that lexical semantics is the study of such encoded aspects of meaning. So, for her, the SS-CS interface would be better called the semantics-pragmatics interface, not the syntax-semantics interface. This makes it seem that her views are very far from those of Jackendoff. Yet Carston's notion of pragmatic enrichment and Jackendoff's notion of enriched composition are very similar.

Jackendoff (2002: 273) does briefly allude to what he might call the semantics-pragmatics interface. It turns out to be an interface level between two sublevels **within** the conceptual system. It is the level that integrates thoughts that are conveyed by means of language with one's previous knowledge, including knowledge of the communicative context and the speaker's intentions. Such integration may lead one to inferentially derive further thoughts (i.e., Gricean implicatures). In other words, Jackendoff's conception is basically the Gricean conception that is rejected by Carston, since it confines pragmatics to the derivation of implicatures, whereas Carston thinks pragmatic processes are also involved in the enrichment of lexical concepts (encoded meanings) to arrive at ad hoc concepts (contextualized meanings). Of course, Jackendoff can use terminology in the way he pleases. However, to make it clearer that his views are in fact very close to those of Carston, it might be more appropriate to relabel Jackendoff's SS-CS interface the syntax-**pragmatics** interface.

This does of course still leave some disagreements unsettled. In particular, it leaves unsettled the issue of syntactocentricism and the debate as to whether there is a specifically linguistic part of semantics, separate from nonlinguistic knowledge, thought, and contextualized meaning. (See Jackendoff, 2002: 281–293, for reasons to deny that there is any such level of semantics.)

Introduction

The science of 'semiotics' – the name adopted by the International Association of Semiotic Studies in 1969 – has been listed under various names (Deely, 2004) by dictionaries and encyclopedias. But it is the term 'semiology' that has always been its primary competitor over the last century. It was Ferdinand de Saussure (1857–1913) who coined the term in the *Cours de linguistique générale* (1916/1969: 68), designating it as the study of "the whole group of systems grounded on the arbitrariness of the sign," which includes "symbolic rites, polite formulas, military signals" (1969: 16). Although 'semiotics' is now the preferred designator of the discipline, 'semiology' has had, and continues to have, a role within it (Clarke, 1987), boasting such users of its paradigm as Valentin Volosinov (1895–1936), Louis Hjelmslev (1899–1965) Roland Barthes (1915–1980), Claude

Semiology and the Focus on Language

M Danesi, University of Toronto, Toronto, Canada

© 2006 Elsevier Ltd. All rights reserved.

Introduction

The science of 'semiotics' – the name adopted by the International Association of Semiotic Studies in 1969 – has been listed under various names (Deely, 2004) by dictionaries and encyclopedias. But it is the term 'semiology' that has always been its primary competitor over the last century. It was Ferdinand de Saussure (1857–1913) who coined the term in the *Cours de linguistique générale* (1916/1969: 68), designating it as the study of "the whole group of systems grounded on the arbitrariness of the sign," which includes "symbolic rites, polite formulas, military signals" (1969: 16). Although 'semiotics' is now the preferred designator of the discipline, 'semiology' has had, and continues to have, a role within it (Clarke, 1987), boasting such users of its paradigm as Valentin Volosinov (1895–1936), Louis Hjelmslev (1899–1965) Roland Barthes (1915–1980), Claude

Lévi-Strauss (1908–), Algirdas Julien Greimas (1917–1992) and Claude Brémond (1929–). The wider orientation towards 'semiotics' and the ideas espoused by Charles S. Peirce (1839–1914) can be traced to the influence of Charles Morris (1901–1979) in the 1940s (Morris, 1938, 1946).

Focus on Language

Saussure indicated in the *Cours* that:

> It is possible to conceive of a science which studies the role of signs as part of social life. It would form part of social psychology, and hence of general psychology. We shall call it *semiology* (from the Greek *semeion*, 'sign'). It would investigate the nature of signs and the laws governing them. Since it does not yet exist, one cannot say for certain that it will exist. But it has a right to exist, a place ready for it in advance. Linguistics is only one branch of this general science. The laws which semiology will discover will be laws applicable in linguistics, and linguistics will thus be assigned to a clearly defined place in the field of human knowledge' (1969: 15–16).

He then went on to classify it as a branch of social psychology and to claim that it would study all signifying phenomena as if they were linguistic ones because, as he puts it: "Signs that are wholly arbitrary realize better than the others the ideal of the semiological process; that is why language, the most complex and universal of all systems of expression, is also the most characteristic" (1969: 68). Further on, he suggested that this is so because: "Without language, thought is a vague uncharted nebula. There are no pre-existing ideas, and nothing is distinct before the appearance of language" (1969: 112).

In the semiological frame, language signs are crucial because they make up the elemental code of the circuit between individuals who are 'unlocking' the contents of each others' brains during communication. Decipherment of the code occurs unconsciously by virtue of the differences that signs bear with respect to each other. This difference gives rise to the possibility of a speech community. That, in essence, constitutes the mode of inquiry espoused by semiology.

Semiology vs. Semiotics

F Nuessel, University of Louisville, Louisville, KY, USA

© 2006 Elsevier Ltd. All rights reserved.

Two terms, 'semiotics' and 'semiology,' and their variants have as their etymological source the Greek word *semeion* 'sign.' The words have different histories, and their entrance into the English lexicon sheds some light on the origin and development of the interdiscipline of semiotics itself. It is for this reason that they are interesting. This article examines these two words briefly in terms of their etymology, orthography, and meaning.

Sebeok (1976: 48) traced the etymology of 'semiotics' to its Greek form *semeiotiké* (<*sema* 'sign' and *semeiotikos* 'observant of signs'), which has a medical reference in its usage for 'symptomatology.' Deely (2003: 1), however, noted that 'semiotics' does not appear as a distinct lexical item with its contemporary meaning in either Greek or Latin. John Locke (1632–1704) employed an untransliterated Greek word (*semeiotiké*) in his *Essay concerning humane understanding* (1689), from which Charles Sanders Peirce (1839–1914) took the word two centuries later.

The orthography of 'semiotics' also merits commentary. Several variants of the now commonly accepted English lexical item 'semiotics' have appeared historically. Sebeok (1976: 48–49) stated that Charles Sanders Peirce, most closely associated with North American semiotics, used several variants in his works: 'semeiotic,' 'semeotic,' and 'semiotic' (his most common usage) but never 'semiotics.' Dictionary entries from the 19th century (1895) have various spellings ('semiotic,' 'semeiotic,' and their plural forms). Sebeok (1976: 50) noted that 'semiotic' in English was launched by Charles Morris (1903–1979) in *Signs, language and behavior* (1946). The use of the expression with final *-s* is certainly by analogy with the closely related *semantics* and *linguistics*. Sebeok noted that the diffusion of 'semiotics' as the currently accepted form began in the mid-1960s.

'Semiotics' has two basic references, as does 'semiology.' First, its earliest Greek allusion refers to a medical meaning, namely, the interpretation of the signs of disease, or symptomatology. Second, its modern signification means the doctrine of signs.

The first appearance of the French word *sémiologie* occurs in the *Dictionnaire de Trévoux* (1752) with its medical meaning. Next, the *Imperial dictionary* of England (1883) contains an entry for 'semeiology,' with the definition 'doctrine of signs,' which predates Ferdinand de Saussure's (1857–1914) use of the French expression *sémiologie* in its current meaning, first in his personal correspondence (1894, 1910), and ultimately in *Cours de linguistique générale* (1916). 'Semiology' is most closely associated with Saussure, who used the expression in its widespread contemporary meaning of '*[a] science that studies the life of signs within society*' (Saussure, 1959: 16, emphasis in original).

The term 'semiotics' has an American English origin, while 'semiology' has a French one. The latter came to the United States under the influence of Saussure's linguistic analytical procedures, while the former traveled to Europe and has become the preferred form today.

Semiosis

W C Watt, University of California, Irvine, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Semiosis is the process of interpreting something as signifying something else, for example, the process of interpreting a south-pointing weathervane as signifying that the local wind is a southerly or of interpreting the word 'unicorn' as signifying ('meaning') an equine creature having a single helical horn and being susceptible to the importunities of virgins. So any act of semiosis is the real-time process of associating a signifier with what it signifies, or a 'representamen' with its 'referent,' in Charles S. Peirce's terminology (1931–1966: § 2.228). Every such act, whether or not exteriorized for transmission (as in Charles Morris

Two terms, 'semiotics' and 'semiology,' and their variants have as their etymological source the Greek word *semeion* 'sign.' The words have different histories, and their entrance into the English lexicon sheds some light on the origin and development of the interdiscipline of semiotics itself. It is for this reason that they are interesting. This article examines these two words briefly in terms of their etymology, orthography, and meaning.

Sebeok (1976: 48) traced the etymology of 'semiotics' to its Greek form *semeiotiké* (<*sema* 'sign' and *semeiotikos* 'observant of signs'), which has a medical reference in its usage for 'symptomatology.' Deely (2003: 1), however, noted that 'semiotics' does not appear as a distinct lexical item with its contemporary meaning in either Greek or Latin. John Locke (1632–1704) employed an untransliterated Greek word (*semeiotiké*) in his *Essay concerning humane understanding* (1689), from which Charles Sanders Peirce (1839–1914) took the word two centuries later.

The orthography of 'semiotics' also merits commentary. Several variants of the now commonly accepted English lexical item 'semiotics' have appeared historically. Sebeok (1976: 48–49) stated that Charles Sanders Peirce, most closely associated with North American semiotics, used several variants in his works: 'semeiotic,' 'semeotic,' and 'semiotic' (his most common usage) but never 'semiotics.' Dictionary entries from the 19th century (1895) have various spellings ('semiotic,' 'semeiotic,' and their plural forms). Sebeok (1976: 50) noted that 'semiotic' in English was launched by Charles Morris (1903–1979) in *Signs, language and behavior* (1946). The use of the expression with final *-s* is certainly by analogy with the closely related *semantics* and *linguistics*. Sebeok noted that the diffusion of 'semiotics' as the currently accepted form began in the mid-1960s.

'Semiotics' has two basic references, as does 'semiology.' First, its earliest Greek allusion refers to a medical meaning, namely, the interpretation of the signs of disease, or symptomatology. Second, its modern signification means the doctrine of signs.

The first appearance of the French word *sémiologie* occurs in the *Dictionnaire de Trévoux* (1752) with its medical meaning. Next, the *Imperial dictionary* of England (1883) contains an entry for 'semeiology,' with the definition 'doctrine of signs,' which predates Ferdinand de Saussure's (1857–1914) use of the French expression *sémiologie* in its current meaning, first in his personal correspondence (1894, 1910), and ultimately in *Cours de linguistique générale* (1916). 'Semiology' is most closely associated with Saussure, who used the expression in its widespread contemporary meaning of '*[a] science that studies the life of signs within society*' (Saussure, 1959: 16, emphasis in original).

The term 'semiotics' has an American English origin, while 'semiology' has a French one. The latter came to the United States under the influence of Saussure's linguistic analytical procedures, while the former traveled to Europe and has become the preferred form today.

Semiosis

W C Watt, University of California, Irvine, CA, USA

© 2006 Elsevier Ltd. All rights reserved.

Semiosis is the process of interpreting something as signifying something else, for example, the process of interpreting a south-pointing weathervane as signifying that the local wind is a southerly or of interpreting the word 'unicorn' as signifying ('meaning') an equine creature having a single helical horn and being susceptible to the importunities of virgins. So any act of semiosis is the real-time process of associating a signifier with what it signifies, or a 'representamen' with its 'referent,' in Charles S. Peirce's terminology (1931–1966: § 2.228). Every such act, whether or not exteriorized for transmission (as in Charles Morris

[1938: 109–112, 30; 1964: 172, 366]), is first of all interior to the creature performing it; in mammals it is mental, or neural, in humans involving most of the brain's 'modules' active in language use plus other semiotic 'modules,' such as those that store and compare sensory inputs like those of vision and hearing, and the reasoning faculty itself.

A semiosis may be evoked by an external stimulus (a real weathervane, perceived as a sign) or solely by an internal thought process (thinking of a unicorn), but the critical factor is that something is taken as a sign and interpreted as signifying something else.

Every act of semiosis resembles a logical deduction, but many such deductions are in the strict sense invalid. What is lacking, resuming our first example, is the 'universal' premise: Every southward-pointing weathervane indicates a local southerly. So the typical semiosis is akin to what Aristotle (e.g., in his *Prior analytics*, 1989 [c. 350 B.C.]: 226–227) identified as an 'enthymeme,' a syllogism missing its universal. To be valid, the universal must be supplied – howbeit tacitly – in what Peirce called a further 'interpretant' (1931–1966, e.g., § 5.284). Even so, most such interpolated universals will come additionally burdened with logically necessary qualifications, some admittedly farfetched: Every southward-pointing weathervane indicates a local southerly unless it is rusted stiff; unless it is being actuated by mischievous rustics; unless it was so poorly designed or built as to indicate a northerly when pointing southward, and so on. Indeed, to achieve validity, many semioses will entail 'interpretants' that are in principle unbounded (... unless this weathervane was perversely magnetized so that its tail turns always toward the Magnetic Pole; unless my eyes deceive me...). Since human time and patience are finite, many of our semioses' signs are tied to their referents mostly by informed guesswork, or in Peirce's phrasing (1931–66, § 2.303), by 'abductions,' *ad infinitum* (and see Watt, 1993: 435–436, note). This holds true for guessing from context the meaning of a language's ambiguous words (*Henry owns a bank*: financial institution or river margin?) and of words whose meaning is known but vaguely (*turgid*, for example) and, not least, for many natural phenomena (e.g., a severe earthquake) when forcibly interpreted by the credulous (e.g., a political disaster is in the offing [Gibbon, n.d., vol. 1: 899–900]).

Since everyday life consists in large part of performing semioses – we think, however darkly, in signs – understanding them as well as we can, at whatever depths we can plumb, is critical to trying to understand everyday life.

Semiosphere

The concept of semiosphere was first put forward by Yuri Lotman in the context of cultural semiotics. He introduced the term in the article 'On Semiosphere' (Lotman, 1984) and elaborated it further in *Universe of the mind* (Lotman, 1990) and *Culture and explosion* (Lotman, 1992). The fundamental insight that underlies Lotman's concept is the notion that the smallest functioning mechanism is not a single sign or single text or single semiotic system, but an entire semiotic space of which the internal organization is created and maintained by multiple sign processes, which occur at different levels of a multifaceted and multileveled system of communication.

Semiosphere is a semiotic space that is necessary for the existence and functioning of languages and other sign systems. All semiotic systems are 'immersed' in a semiotic space and "can only function by interaction with that space" (Lotman, 1990: 125). A sign cannot make sense except in the context of other signs. In other words, semiosphere is a sphere of semiosis and **an experience thereof**; and, as such, it is a prerequisite for any single act of communication to

[1938: 109–112, 30; 1964: 172, 366]), is first of all interior to the creature performing it; in mammals it is mental, or neural, in humans involving most of the brain's 'modules' active in language use plus other semiotic 'modules,' such as those that store and compare sensory inputs like those of vision and hearing, and the reasoning faculty itself.

Semiosphere versus Biosphere

Semiosphere

The concept of semiosphere was first put forward by Yuri Lotman in the context of cultural semiotics. He introduced the term in the article 'On Semiosphere' (Lotman, 1984) and elaborated it further in *Universe of the mind* (Lotman, 1990) and *Culture and explosion* (Lotman, 1992). The fundamental insight that underlies Lotman's concept is the notion that the smallest functioning mechanism is not a single sign or single text or single semiotic system, but an entire semiotic space of which the internal organization is created and maintained by multiple sign processes, which occur at different levels of a multifaceted and multileveled system of communication.

Semiosphere is a semiotic space that is necessary for the existence and functioning of languages and other sign systems. All semiotic systems are 'immersed' in a semiotic space and "can only function by interaction with that space" (Lotman, 1990: 125). A sign cannot make sense except in the context of other signs. In other words, semiosphere is a sphere of semiosis and **an experience thereof**; and, as such, it is a prerequisite for any single act of communication to

be interpreted as one. Lotman's insistence on the prior existence of semiotic space in relation to single texts as well as to the interrelationship of texts within semiosphere has an analogue in C. S. Peirce's principle *omne symbolum e symbolo*. In biology, an analogical relationship has been formulated as Redi's law: *omne vivum e vivo*. Another version of it is Jakob von Uexküll's (1920: 6) 'every design is from design.'

Some fundamental assumptions about the structural properties of the semiotic space of culture have been formulated already in the *Theses on the semiotic study of cultures*:

> In the study of culture the initial premise is that all human activity concerned with the processing, exchange, and storage of information possesses a certain unity. Individual sign systems, though they presuppose immanently organized structures, function only in unity, supported by one another. None of the sign systems possesses a mechanism which would enable it to function culturally in isolation (Ivanov *et al.,* 1998 [1973]: 33).

These statements, along with the insistence on the fundamental duality between verbal (discrete) and pictorial (iconic) modeling systems (i.e., 'code duality'), form the basis of Lotman's writings throughout his scholarly career. Yet, the concept of semiosphere marks a shift from strictly structuralist concerns to, addressing more explicitly, the dynamics and organicism (cf. Mandelker, 1994) of cultural systems.

The concept of semiosphere draws on an analogy to Vladimir I. Vernadsky's concept of biosphere. In his letter to Boris Uspensky, written in 1982, Lotman first outlines his position:

> While reading Vernadsky, I was stunned by one of his statements. You know ... my opinion that a text can exist (i.e., is socially acknowledged as a text) if another text precedes it, and that any advanced culture must have been preceded by an advanced culture. And now I have discovered Vernadsky's thought, deeply founded on experience of exploring cosmic geology, that life can originate only from the living, i.e., only if it is preceded by it [...] Only the antecedence of semiotic sphere makes message out of message. Only the existence of intellect explains the existence of intellect (Lotman, 1997: 630).

Lotman interprets Vernadsky's concept of biosphere as the totality and the organic whole of living organisms and life processes. Accordingly, he proposes that semiosphere is to be understood as the totality of texts, languages, and sign processes that are interconnectedly bound to each other. Mihhail Lotman has pointed out that this assumption has a necessary methodological implication: "In the field of culture simple models do not precede the complicated ones, but, vice versa, simple models are the result of investigator's abstraction or the result of reduction or degeneration of complicated systems" (Lotman, 2001: 98). The concept of semiosphere as put forward by Lotman forms the core of the holistic theory of culture that departs from the assumption that "the unit of semiosis, the smallest functioning mechanism is not a separate language, but the whole semiotic space of culture in question" (Lotman, 1990: 125). **The elementary unit of semiosis is semiosphere.**

Functionally, semiosphere can be characterised as a 'thinking' system that is able to: (1) transmit available information; (2) create new information that is not simply deducible according to a set of algorithms from already existing information, but which is to some degree unpredictable; and (3) preserve and reproduce information, that is, any semiotic system has its own memory. Semiosis in this system can be understood mainly in terms of translation and dialogue. "Translation is a primary mechanism of consciousness. To express something in another language is a way of understanding it" (Lotman, 1990: 127). The need for dialogue, the dialogic situation precedes both the real dialogue and the existence of a language in which to conduct it: dialogic situation creates the common language that underlies the translation of messages (143).

One of the most important categories in the semiosphere is that of **boundary**. The system is able to engage in dialogic processes only if its structural identity is established. The beginning point for semiotic individuation is the binary distinction of 'inside' versus 'outside': the boundary of the semiosphere can be defined as the outer limit of a first-person form. Therefore, semiosphere is a 'bounded' system in the sense that it is distinguished from and cannot have contact with nonsemiotic or alien semiotic systems. On the other hand, semiotic boundary is to be conceived as an abstraction, a series of bilingual filters or membranes that enable the translation of messages from one semiotic system to another. In this way, boundary that is defined as an at least double-coded system of translation filters both determines the identity of the system and allows the translation of messages between the different semiotic systems.

The category of 'boundary' leads to two further characteristics of semiosphere: **binarism** and **asymmetry**. The translation mechanism responsible for the generation of new meaning in semiosphere presupposes at least two semiotically different participants that are mutually untranslatable. The entire space of the semiosphere is transected by boundaries and "since in the majority of cases the different languages of the semiosphere are semiotically asymmetrical, i.e., they do not have mutual semantic correspondences, then the whole semiosphere can be regarded as a

generator of information" (Lotman, 1990: 127). Asymmetry is also manifest in the relationship between 'center' and 'periphery,' between the defining core that tends toward the 'homogeneity' in the semiosphere through the mechanisms of 'autocommunication,' and the accelerated semiotic processes (fluctuations) that reveal the internal heterogeneity of the semiosphere.

It follows from the above statements that, firstly, the unity of semiosphere is always a more-or-less phenomenon and can be conceived only insofar as we consider the 'self-description' of the given system: the semiosphere is marked by heterogeneity. It is filled up with multiple semiotic systems "that relate to each other along the spectrum which runs from complete mutual translatability to just as complete mutual untranslatability" (Lotman, 1990: 125). Secondly, at all stages of contact, semiosphere comes into connexion with other semiotic systems that formerly lay beyond the boundaries of the semiosphere. Thirdly, the dynamics of the subsystems within the semiosphere are marked by heterogeneity as well. As a conclusion, semiosphere can be described as a 'semiotic continuum,' a heterogeneous yet bounded space that is in constant interaction with other similar structures. The points of contact between different systems (which, in turn, are part of a heterogeneous space of a higher order) enable the emergence of new meaning, that is, the deviation from the already established codes, models, or habits of the given system.

The concept of semiosphere also reflects the influence of the theory of self-organizing systems proposed by Ilya Prigogine and Isabelle Stengers (1984). For Lotman, Prigogine's ideas have two important implications. First, the stochastic and lawful (chance and necessity) are revealed as two sides of the same coin. Secondly, this leads to the separation in time and causality. This enabled Lotman to formulate a non-progressive view on dynamics of culture where the rapid (stochastic, explosive) processes in culture alternate with the periods of normal development. Semiosphere thus appears as a self-organizing system that undergoes constant renewal due to the emergence of new meanings created in the process of internal and external translation. Indeed, the basic mechanism for the creation of new meanings in culture appears to be the existence of a certain amount of misunderstanding or miscommunication that is built into the very structure of its semiotic space while the structural stability of any semiotic system is maintained by the self-descriptions created by the system in the process of autocommunication. The communication between different semiotic systems tends towards the increase in heterogeneity while autocommunication tends towards the increase in homogeneity.

Biosphere

Biosphere is a global network of life, a self-regulating system that embraces both the living organisms (biota) and their abiotic environment to the extent it is involved in the processes of life, including the troposphere, the ocean, and the upper envelopes of the earth crust. Living matter, dispersed in the form of living organisms and sharply separated from its inert environment, is the most important source of self-regulation and stability in the biosphere.

The foundational treatises on biosphere (and a conception related to it, noosphere) are attributed to Pierre Teilhard de Chardin and Vladimir I. Vernadsky. However, the modern usage of the term 'biosphere' began with Eduard Suess, a palaeontologist and geologist at the University of Vienna, who adopted the term in 1875. His brief account is, however, ambivalent and can be interpreted as referring either to (1) the sum total of living organisms, or (2) a geosphere created and organized by the life processes. The former view was taken up by Teilhard de Chardin while Vernadsky combines the two meanings to account for the biosphere as a geological envelope and a self-organizing system.

For Vernadsky, the biosphere is defined by the "cyclical processes of atom exchange between living matter and inert matter in the biosphere" (Vernadski, 1977: 111), i.e., the biogenic migration of atoms. The processes of atom migration are also a fundamental source of change in the biosphere. According to the principles of biogeochemistry formulated by Vernadsky, the evolution in the biosphere is an irreversible process that proceeds "in the direction of increasing the level of self-regulation and stability" (Levit, 2001: 61). One of the basic methods to achieve this is "to increase the intensity and the complexity of biogenic migration of atoms" (65), i.e., the basic determinant in the evolution of the biosphere is the growth of the atom exchange caused by the life processes:

> The biosphere appears in biogeochemistry as a peculiar envelope of the Earth clearly distinct from the other envelopes of our planet. The biosphere consists of some concentric contiguous formations surrounding the whole Earth and called geospheres. The biosphere has possessed this perfectly definite structure for billions of years. This structure is tied up with the active participation of life, is conditioned by life to a significant degree and is primarily characterised by dynamically mobile, stable, geologically durable equilibria which, in distinction from mechanical structures are quantitatively fluctuating within certain limits in relation to both space and time (Vernadsky, 1977: 120).

One of Vernadsky's most fundamental assumptions is that living and inert natural bodies are connected only by a biogenic flow of atoms: living matter in biosphere is embedded in its inert environment, yet it is clearly distinct from it from both structural and energetic points of view in that it constitutes an independent space-time that functions according to its own laws. There are almost no transitional forms between living and inert matter. Vernadsky draws here on the observations made by Louis Pasteur and Pierre Curie about the molecular dissymmetry discerning living organisms from inert matter: for dissymmetry to occur, it presupposes a space in which its organization is also dissymmetrical. In other words, dissymmetrical effects can be brought about only by a dissymmetrical cause. This assumption leads to one of the most important statements in Vernadsky's theory: the impossibility of abiogenesis in biosphere, or that life presupposes life but also that life appears from the very beginning in the form of the biosphere. According to Vernadsky, then, biosphere is what we might call an emergent phenomenon.

The Gaia Hypothesis

In 1968, James Lovelock proposed the so-called Gaia hypothesis, which states that the physical conditions of the Earth's surface, oceans, and atmosphere have been made fit for life and, as well, have been maintained in this state by the living organisms themselves. According to a definition proposed by Lovelock, Gaia is

> a complex entity involving the Earth's biosphere, atmosphere, oceans, and soil; the totality constituting a feedback or cybernetic system which seeks an optimal physical and chemical environment for life on this planet. The maintenance of relatively constant conditions by active control may be conveniently described by the term 'homoeostasis' (Lovelock, 1979: 10).

In this respect, Vernadsky's concept of biosphere as a self-regulating system anticipates many crucial claims put forward in Lovelock's Gaia hypothesis.

Noosphere

According to Vernadsky, by the beginning of the 20th century, biosphere had evolved through a transitional period from biosphere to noosphere. In this stage, the central stabilizing force would not be living matter but human thought, or, more precisely, scientific thought. In this respect, the latter is a function of the biosphere and thus a geological phenomenon. Therefore, in noosphere, the functions of the biogenic energy created by living matter would be taken over by "the energy of human culture" – a term coined by Vernadsky to denote the transformative force created by the activity of human mind.

The rise of civilization is a geological necessity; its continuous development is related to the dissymmetry of time in living matter whose function is scientific thought. According to Vernadsky,

> a civilization of 'cultural humanity' (being a form of a new geological force created in the biosphere) *cannot disappear or cease to exist*, for it is a great natural phenomenon corresponding historically, or more correctly, geologically, to the established organization of the biosphere. Forming the noosphere, the civilization becomes connected through all its terrestrial roots to its terrestrial envelope (*biosphere*), which has never happened in the previous history of mankind to a comparable degree (Vernadsky, 1977: 33; English quotation in Levit, 2001: 77).

Noosphere, therefore, is not a layer **in** the biosphere but it **is** the biosphere, where the central role belongs to the "energy of human culture," to "scientific thought" (Vernadsky, 1977: 95).

Teilhard de Chardin considered biosphere as an aggregate of terrestrial living organisms. Accordingly, Teilhard's noosphere is a "thinking layer" (Teilhard de Chardin, 1967: 202), one more envelope around and over the biosphere, its appearance marking not the next stage in the evolution of the biosphere but the rise of the split between the intelligence and its material matrix leading to the death of the Earth. Therefore, noosphere is only a transitional stage in the further development of supreme consciousness, "the end of all life on our globe, the death of the planet, the ultimate phase of the phenomenon of man" where "mankind, *taken as a whole*, will be obliged [...] to reflect upon itself at a single point" (Teilhard de Chardin, 1967: 300, 315). Little by little, the human minds extend

> the radius of their influence upon this earth which, by the same token, shrank steadily [...] Through the discovery yesterday of the railway, the motor car and the aeroplane, the physical influence of each man, formerly restricted to a few miles, now extends to hundreds of leagues or more. Better still: thanks to the prodigious biological event represented by the discovery of electromagnetic waves, each individual finds himself henceforth (actively and passively) simultaneously present, over land and sea, in every corner of the earth (Teilhard de Chardin, 1967: 240).

This paragraph from Teilhard de Chardin was later recalled by Marshall McLuhan in a passage discussing the "new electronic interdependence" that "recreates the world in the image of a global village": "This externalization of our senses creates what de Chardin calls the 'noosphere' or a technological brain of the world" (McLuhan, 1962: 31–32).

One must make a clear distinction between semiosphere and noosphere: "The existence of noosphere

is material and spatial, it encompasses a part of our planet, whereas the space of semiosphere is of an abstract kind" (Lotman, 1984: 6). However, as noted by Vjačeslav V. Ivanov, the noosphere is unthinkable without the semiosphere (Ivanov, 1998: 792).

Biosphere as Semiosphere

In the semiotic context, Thomas A. Sebeok has defined biosphere as "that parcel of the planet earth which comprises life-signs [...] The biosphere is where we live and what we are; but, although it is the only domicile we possess thus far, we are neither its sole inhabitants or constitute anything approaching a plurality in – let alone tenured – occupancy" (Sebeok, 1997: 113).

In 1993, Danish biosemiotician Jesper Hoffmeyer adopted the term 'semiosphere' (independently of Lotman) to designate the totality of semiotic processes occurring on planet Earth. According to Hoffmeyer, semiotic quality of life manifests itself in the tendency to acquire habits, that is, in the tendency to evolve into new regularities.

> Living systems exhibit extreme semiogenic behaviour through the process I have termed 'semetic interaction.' Semetic interactions refer to interactions in which regularities (habits) developed by one species (or individual) successively become used (interpreted) as signs by the individuals of the same or another species, thereby eliciting new habits in this species eventually to become – sooner or later – signs for other individuals, and so on in a branching and unending web integrating the ecosystems of the planet into a global semiosphere (Hoffmeyer, 1998: 287).

Accordingly,

> the semiosphere is a sphere just like the atmosphere, the hydrosphere, and the biosphere. It penetrates to every corner of these other spheres, incorporating all forms of communication: sounds, smells, movements, colors, shapes, electrical fields, thermal radiation, waves of all kinds, chemical signals, touching, and so on. In short, signs of life (Hoffmeyer, 1996: vii).

Hoffmeyer departs from the semiotic theory of Peirce by considering semiosis central to the understanding of life processes: "signs, not molecules are the basic units in the study of life" (Hoffmeyer, 1997b: 940). In this perspective, semiosphere (the sphere of semiosis) coincides with biosphere (the sphere of life). However, Hoffmeyer goes even further by arguing that from the semiotic point of view, "biosphere appears as a reductionist category which will have to be understood in the light of the yet more comprehensive category of the semiosphere" (Hoffmeyer, 1997a: 934). "We tend to overlook the fact that all plants and animals – all organisms, come to that – live, first and foremost, in a world of *signification*. Everything an organism senses signifies something to it ..." (Hoffmeyer, 1996: vii).

Similar conceptions of semiobiosphere and biosemiosphere have been described in semiotic literature by, respectively, Augusto Ponzio and Susan Petrilli, and Floyd Merrell. Both accounts depart from the original concept by Lotman and introduce it into the Peircean theoretical framework. Ponzio and Petrilli identify the semiosphere with biosphere and provide an integrated view of semiobiosphere that "obviously includes the *semiosphere* as constructed by human beings, by human culture, signs, symbols and artifacts, etc." (Ponzio and Petrilli, 2001: 264–265, original emphasis). However, they also underline that "the semiosphere is part of a *far broader* semiosphere, the semiobiosphere – a sign network human beings have never left, and to the extent that they are *living beings*, never will" (265, original emphasis). Merrell (2001) follows similar assumptions.

Fields of Signs

The domain of semiotic anthropology is here considered to be results of empirical research carried out by anthropologists (in all subfields) that makes use of concepts and methods associated with the tradition of scholarship labeled 'semiotics' or 'semiology.' Semiotic anthropology is not a formal subdiscipline of anthropology; it is not a school of anthropological thought; and it is not confined to researchers affiliated with particular academic institutions or national traditions. To some degree semiotic anthropology emerged as a correction and refinement of symbolic or interpretive anthropology or structural anthropology (Mertz, 1985). In addition to the study of linguistic and written codes, anthropologists have employed semiotic notions in the analysis of cultural signs such as pictorial representation and images, dress and bodily adornment, gesture and dance, spatial organization and the built environment, ritualized behaviors (taboo, divination, performance), exchange valuables, and food and cuisine. Although anthropology has played a relatively minor role in the development of the larger discipline of semiotics, which is dominated by literary studies, it was an anthropologist, Margaret Mead (1901–1978), who coined the modern label at an interdisciplinary conference at Indiana University in 1962. In her summary comments, Mead discussed the possibility of a new term

> which in time will include the study of all patterned communication in all modalities, of which linguistics is the most technically advanced. If we had a word for patterned communication modalities, it would be useful. I am not enough of a specialist in this field to know what word to use, but many people here, who have looked as if they were on opposite sides of the fence, have used the word "semiotics." It seems to me the one word, in some form or other, that has been used by people arguing from quite different positions (Mead, 1964: 275).

Like all aspects of contemporary research in semiotics, semiotic anthropology is heir to two dominant intellectual strands stemming from work of the American scientist and mathematician Charles S. Peirce (1839–1914) and the Swiss linguist Ferdinand de Saussure (1857–1913). Peirce and Saussure did not know of each other; much of their writing on semiotics or semiology is fragmentary and took decades to become widely available; and neither discussed strictly anthropological topics with any specificity.

Peirce developed an innovative reformulation of valid scientific reasoning by viewing both human thought and natural processes as following the inferential logic of signs or 'semeiotic.' For Peirce the universe was perfused with signs that stand for or

Fields of Signs

The domain of semiotic anthropology is here considered to be results of empirical research carried out by anthropologists (in all subfields) that makes use of concepts and methods associated with the tradition of scholarship labeled 'semiotics' or 'semiology.' Semiotic anthropology is not a formal subdiscipline of anthropology; it is not a school of anthropological thought; and it is not confined to researchers affiliated with particular academic institutions or national traditions. To some degree semiotic anthropology emerged as a correction and refinement of symbolic or interpretive anthropology or structural anthropology (Mertz, 1985). In addition to the study of linguistic and written codes, anthropologists have employed semiotic notions in the analysis of cultural signs such as pictorial representation and images, dress and bodily adornment, gesture and dance, spatial organization and the built environment, ritualized behaviors (taboo, divination, performance), exchange valuables, and food and cuisine. Although anthropology has played a relatively minor role in the development of the larger discipline of semiotics, which is dominated by literary studies, it was an anthropologist, Margaret Mead (1901–1978), who coined the modern label at an interdisciplinary conference at Indiana University in 1962. In her summary comments, Mead discussed the possibility of a new term

> which in time will include the study of all patterned communication in all modalities, of which linguistics is the most technically advanced. If we had a word for patterned communication modalities, it would be useful. I am not enough of a specialist in this field to know what word to use, but many people here, who have looked as if they were on opposite sides of the fence, have used the word "semiotics." It seems to me the one word, in some form or other, that has been used by people arguing from quite different positions (Mead, 1964: 275).

Like all aspects of contemporary research in semiotics, semiotic anthropology is heir to two dominant intellectual strands stemming from work of the American scientist and mathematician Charles S. Peirce (1839–1914) and the Swiss linguist Ferdinand de Saussure (1857–1913). Peirce and Saussure did not know of each other; much of their writing on semiotics or semiology is fragmentary and took decades to become widely available; and neither discussed strictly anthropological topics with any specificity.

Peirce developed an innovative reformulation of valid scientific reasoning by viewing both human thought and natural processes as following the inferential logic of signs or 'semeiotic.' For Peirce the universe was perfused with signs that stand for or

represent their objects and that determine further interpretant signs, which in turn represent the relationship between the processually prior signs and their objects. Refusing to take natural language as the model semiotic system but recognizing the special character of conventional linguistic forms (which he called, following Aristotle, symbols), Peirce subdivided the opposed traditional category of natural signs (Greek *semeion*) into icons, which resemble their objects in some formal way, and indexes, which are spatially or temporally contiguous with their objects.

> A sign endeavors to represent, in part at least, an Object, which is therefore in a sense the cause, or determinant, of the sign even if the sign represents its object falsely. But to say that it represents its Object implies that it affects a mind, and so affects it as, in some respect, to determine in that mind something that is mediately due to the Object. That determination of which the immediate cause, or determinant, is the Sign, and of which the mediate cause is the Object may be termed the Interpretant (Peirce, 1934–1935: 237; CP 6:347).

Of the three Peircean grounds relating signs and objects, only symbolic conventionality requires the interpretant to supply the linkage between sign and object, although nothing actually functions as a sign unless it is interpreted to be a sign of some sort. Peircean symbols are, thus, irreducibly triadic; but symbols can communicate information about their objects only by embodying icons and can successfully point to the external world only by embodying indexes, which anchor the contextual flow of signs (or semiosis) so that potential interpreters can bring their collateral knowledge to bear on the objects being represented. A scientist of international stature and a strong exponent of the pragmatic theory of truth, Peirce was not at all sensitive to the imperfections and limitations of cultural sign systems, even preferring to employ his own artificial system of existential graphs as a calculus for reasoning. In thinking about both the linguistic and graphic diagrammatization of inferential thought, Peirce insisted that the particular form of symbolization is irrelevant to the constitution of meaning, and that a language is usable to the degree that its system of formal representation transparently mirrors the process of valid logical inference (Parmentier, 1994: 42–43). Of considerable impact in contemporary semiotic anthropology are passages in which Peirce suggests that, since all thought is in signs, a thinking person is not very different from a sign, and, furthermore, that the interior process of thought does not differ in principle from dialogical communication between people.

> There is no element whatever of man's consciousness that has not something corresponding to it in the word; and the reason is obvious. It is that the word or sign that man uses is the man himself. For, as the fact that every thought is a sign, taken in conjunction with the fact that life is a train of thought, provides that man is a sign; so, that every thought in an external sign, proves that man is an external sign . . . Thus my language is the sum total of myself; for the man is the thought (Peirce, 1934–1935: 189; CP 5.314).

Saussure continued the classical and medieval tradition of viewing the linguistic sign (*signe*) as a dual entity, conjoining a perceptible expression or 'signifier' (*signifiant*) with an intelligible concept or 'signified' (*signifié*). The signifying relationships that bind the two levels of the sign fall along a continuum from radical arbitrariness, where there are no external constraints on the linkage between expression and conception, to relative motivation, where the relational, systemic complexity or the value of the linguistic forms – considered in terms of linear sequence (the syntagmatic axis) and in terms of associative sets (the paradigmatic axis) – imposes a limitation on arbitrariness. In order to uncover the dynamic relationship between continuity and change in linguistic signs, Saussure adopted the methodological principle of separating actual events of speaking (*parole*) from the social conventions that stipulate the meaning of signs for members of a community (*langue*). Although his primary focus was on language as a semiological system, Saussure mentioned in passing a number of other cultural systems, such as maritime signals, religious icons, and gestural codes, where the component units that do not display the radical arbitrariness of linguistic signs are better called symbols. By replacing the view of language as nomenclature with the proto-structuralist notion that oppositional relations among signs constitute the system of *langue*, Saussure recognized that languages, and by extension other semiological systems, do not slice up conceptual space in the same ways.

A detailed comparison of Peirce and Saussure cannot be attempted here, but three points need to be made briefly. First, anthropological research following either Peirce or Saussure needs to be aware of the terminological confusion stemming from the fact that the Peircean symbol correlates with the Saussurean *signe*, and the Saussurean *symbole* is defined by the presence of iconic and indexical linkages. Second, there is a fundamental divergence between Peirce's keen attention to the token-level instantiation of general signs and to the contextual rootedness of semiosis and Saussure's omission of the referent from his basic notion of the sign and of events of speaking from his model of the linguistic system. And third, research

in semiotic anthropology has begun to demonstrate clearly that Peircean and Saussurean approaches are in fact complementary, in the sense that the strengths of one theorist are matched by a correlative weaknesses in the other (Parmentier, 1994: xiii–xv).

Foundations of Semiotic Anthropology

The Russian-born linguist Roman Jakobson (1896–1982) is certainly the pivotal figure in the development of semiotic anthropology. During summer holidays as a young student, Jakobson collected folklore (especially proverbs and epic tales) and recorded dialect data; with student friends (including the slightly older folklorist Petr Bogatyrev [1893–1971]) he went on fieldwork expeditions in 1915 and 1916 in the Vereja Region near Moscow. Jakobson's close association with Bogatryrev continued during their years together as members of the Prague Linguistic Circle; and in 1929 they published a short paper on creativity in folklore and literary language. Citing the Saussurean distinction between particular speech events (*parole*) and the set of conventions accepted by a community (*langue*), the authors noted that "like langue, the work of folklore is extra-personal and has only a potential existence. It is only a complex of certain norms and impulses, a canvas of living tradition, which the performers animate with the embellishments of individual creativity, just as the creators of parole do in relationship to langue" (Bogatyrev and Jakobson, 1982: 38). But they then go on to point out an important distinction between oral and written traditions: a 'work' appears as langue to the performers of folklore, that is, as extra-personal, whereas the author of a literary 'work' regards it as parole. They warn, however, against the naïve view that folklore can only be produced by a homogeneous society with a singular collective personality and that literary culture is totally isolated from the influence of legends, superstitions, and myth-making.

Bogatyrev continued his fieldwork among the Carpathian Ukranians (1923–1926) and his engagement as a scholar and performer of contemporary theater. In a series of papers written in the 1930s, he sought to synthesize Karl Bühler's functional approach to language and V. N. Vološinov's semiotic approach to language and material culture in arguing that tangible things become signs when they acquire meaning beyond the bounds of their existence as a practical thing, just as speech confers meaning on the phonemes of a language: "Some objects can be used equally as material things and signs; for instance costume with its several functions is a material thing and a sign at the same time ... Cases where costume is only a sign are quite rare. Even the Chinese actor's paper costume, which functions predominantly to signify that the actor is playing the role of a Chinese, is, after all, not only a sign but also something that covers the actors's body" (Bogatyrev, 1976: 14). Bogatyrev noted this same multifunctionality in the language of the stage: "In some cases, the dominant function of the speech of a dramatic character may lie not in the content of the speech as such but in those verbal signs that characterize the nationality, the class, and so forth, of the speaker ... A speech that is full of mistakes may designate not only a foreigner but usually also a comic character" (Bogatyrev, 1976: 36–37). From the point of view of the audience, then, the actor is a "system of signs" (Bogatyrev, 1976: 48). Bogatyrev was one of the first to apply semiotic and structural methods to cultural data beyond language, and his monograph on folk costume, which introduced the notion of the "function of the structure of functions," anticipated both French and British versions of structuralism in anthropology (Bogatyrev, 1971: 96).

At the International Congress of Slavic Philologists meeting in Prague in 1929, a steering committee from the Prague Linguistic Circle presented a unified text expressing their views on the nature of language and verbal art. A key point in these 'Theses' is the definition of the 'aesthetic function' (adding to the three functions identified by Bühler) as the focus on the level of signs or expression (also called the message in later formulations): "From the thesis that poetic speech is directed at expression itself it follows that all the levels of a system of language that play only an ancillary role in communicative speech acquire a greater or lesser autonomous value in poetic speech. The linguistic devices grouped in these levels and the interrelation among the levels, often automatized in communicative speech, tend to become deautomatized in poetic speech" (Jakobson *et al.*, 1982: 15). A second influential idea involves the systemic nature of cultural phenomena:

> There can be no doubt that poetry is a self-contained entity set apart by its own signs and determined as an entity by its own dominant feature: poeticity. But it is also a part of higher entities, a component part of culture and the overall system of social values. Each of these autonomous yet integral parts is regulated by immanent laws of self-propulsion, while at the same time depending upon the other parts of the system to which it belongs; if one component changes, its relationship to the other component changes, thereby changing the components themselves. With the invention of photography, the goals and structures of painting changed; with the invention of the motion picture, the goals and structure of the theater changed (Jakobson, 1976: 180).

This broader ideological context can be a matter of a culture's semiotic ideology, as Jakobson notes in an analysis of the Hussite's rationalistic attack on the mystical symbolism of the medieval Gothic period: in challenging the symbolic nature of religious icons and liturgical rites, the Hussites rejected the "dialectical unity of form and content, of image and thing, of sign and object signified – the dialectical unity that forms the basis of medieval art and philosophy" (Jakobson, 1976: 181). And a third idea is that Saussure's strict separation of synchrony and diachrony needs to be overcome by the recognition that language changes reflect the "needs of the system" and that phenomena such as stylistic archaism and unproductive forms are evidence of diachrony within synchrony.

Jakobson's extensive research on parallelism in both verse and prose has proven highly influential for comparative studies in linguistics and semiotics (see Fox, 1977). Reflecting on his days as a student hearing a famous female storyteller recite epic verse and on his subsequent analyses of parallelism in syntactic constructions, grammatical forms, lexical identities, and prosodic schemes, Jakobson confessed, "Apparently there has been no other subject during my entire scholarly life that has captured me as persistently as have questions of parallelism" (Jakobson and Pomorska, 1983: 100). These contributions exemplify his effort to take Saussurean concepts (here, the axes of selection and combination) and project them into veritable anthropological analyses of events of speaking and complex aesthetic constructions.

Anthropololgy Meets Semiotics

An early conjuncture of British anthropology and semiotics occurred in *The meaning of meaning* by C. K. Ogden and I. A. Richards, first published in 1923. The book includes an appendix containing extended excerpts from several of Peirce's published papers (1868–1906) and from his unpublished correspondence with Lady Victoria Welby (1904–1909) and a supplementary essay by Bronislaw Malinowski titled 'The problem of meaning in primitive languages.' This book, which went through five editions, is the first place that Peirce's ideas about semeiotic received wide attention. Although it does not appear that Malinowski was aware of the Peirce texts when composing his essay (and he does not employ Peircean terminology), there are several points of convergence between Malinowski's view of the "essentially pragmatic character" (1938: 316) of language and Peircean semiotics, including the focus on the contextual grounding of linguistic signs, the multiple functions of acts of speaking, and the refusal to reify meaning as the inherent property of lexemes.

A much more direct and productive conjuncture of anthropology and semiotics occurred in 1942–1943 when Claude Lévi-Strauss and Roman Jakobson attended each others' lectures at the Free School of Advanced Studies in New York City. Levi-Strauss's lectures dealt with comparative study of kinship systems, and Jakobson presented six lectures on sound and meaning and another series of lectures on Saussure. From his later reflections on these contacts, it is clear that it was the structural approach of Jakobson's phonological theory more than the general semiotic orientation that inspired Lévi-Strauss to found structural anthropology.

> It cannot be doubted that these lectures also make an important contribution to the human sciences by emphasizing the role played in the production of language (but also that of all symbol systems) by the unconscious activity of the mind. For it is only on condition that we recognize that language, like any other social institution, presupposes mental functions that operate at the unconscious level, that we can hope to reach, beyond the continuity of the phenomena, the discontinuity by those "principles by which language is organized" (Lévi-Strauss, 1978: xviii–xix).

From the premise that the invention of language is the defining development in the transition between the state of nature and the state of culture, Lévi-Strauss draws the inference that cultural analysis should follow the guidelines of linguistic analysis: "Because language is the most perfect of all those cultural manifestations which, in one respect or another, constitute systems, and if we want to understand art, religion or law, and perhaps even cooking or the rules of politesse, we must imagine them as being codes formed by articulated signs, following the pattern of linguistic communication" (Lévi-Strauss, 1969: 150–151).

While Lévi-Strauss clearly grounds structuralism in language, he generalized this approach to encompass other codes of communication, some relying on articulate language as their primary code and others operating independently of the linguistic code. But each of these languages must meet the qualification of being a system of signs "transformable, in other words **translatable**, into the language of another system with the help of substitutions" (Lévi-Strauss, 1976: 19).

By synthesizing methods of structural linguistics from Saussure and Jakobson with the insights from information theory as formulated by Claude Shannon, Lévi-Strauss attempts to formulate the similarities and differences of systems of signs such as affinal exchange, economic transactions, religious rites, and

mythological narratives, by employing semiotic concepts to differentiate these homologous communication systems. He puts speech and kinship alliance at opposite ends of a continuum, according to which the former exchanges words that are purely signifying signs (that is, mechanisms for the schematization of thought, without affective, possessive, or magical associations) and the latter exchanges marriageable women that continue to be both signs and values.

Two critical invariants are found in all these semiological systems: at the token level, all involve social activity mediated by the reciprocal exchange of messages, whether words, women, goods, or offerings; at the type level, the meaning of these messages is constituted not by motivated or analogous ties with isolated external referents but by the positional value of signs as part of systemic codes. The combination of these two fundamental invariants guarantees that cultural analysis will continue to be grounded in worldly realities functioning primarily as signifiers rather than as signifieds.

> One cannot study gods while ignoring their images; rites without analyzing the objects and substances manufactured and manipulated by the officiant; or social rules independently of the things that correspond to them. Social anthropology does not confine itself to a part of the domain of ethnology; it does not separate material culture and spiritual culture. Men communicate by means of symbols and signs. For anthropology, which is a conversation of man with man, all things are symbol and sign which act as intermediaries between two subjects (Lévi-Strauss, 1976: 11).

For Lévi-Strauss to prove his point that semiological value flows from the system and not from reference, he needs to analyze some cultural phenomenon in which the elementary units are not semantically motivated but rather are purely positional, that is, where the units resemble phonemes rather than lexemes. Myths serve this purpose well, since not only do mythic elements or 'mythemes' acquire significance due to their position in paradigmatic sets that are not part of the narrative sequence, but myths as a whole are subject to constant transformation across spatial and temporal boundaries.

It is precisely this relationship between event and system that provides Lévi-Strauss with a primary mode of typologizing the cognitive worlds of various societies, which he divides into the "savage mind," a cognitive style that works to deny the impact of historical contingency on systems of cultural classification, the "scientific mind," thinking that internalizes the historical process as the principle of development. This typological opposition is then expressed in terms of semiotic phenomena: the distinction between the dimensions of the sign as correlating a percept (that is, a sensory perception) and a concept (that is, a signified meaning) provides a metalanguage for comparison. Lévi-Strauss contrasts the engineer and the myth-teller as oriented respectively toward the intelligible signified and the perceptible signifier; the former tries to employ signs that are maximally transparent to known reality, while the latter forever generates new narratives out of the detritus of previous myths. He is careful to point out, however, that the distinction between mythological and scientific mentalities does not imply different degrees of rationality in contrasting types of societies, only different kinds of rationality. To further avoid the taint of evolutionary positivism, he notes that examples of each mentality are easy to find in the other kind of society: just as the famous *bricoleur* or 'handyman' who works by means of materials ready-to-hand manifests the savage mind within industrialized society, so the *churinga*, a sacred object that is the material embodiment of ancestral action in the past, indexes diachrony or pure historicity for Australian aborigines.

Peirce in Semiotic Anthropology

Just as Jakobson's revolutionary phonological theory and constructive critique of Saussure were providing Lévi-Strauss with a model for his semiological view of anthropology, Jakobson himself was making his first acquaintance with the writing of Peirce in the early 1950s. A 10-volume edition of Peirce's writings started to appear in print in 1931 under the editorship of Charles Hartshorne and Paul Weiss, both philosophy instructors at Harvard University, where Jakobson began teaching in 1949. Asked to summarize the results of the joint Conference of Anthropologists and Linguists held at Indiana University (Bloomington) in 1952, Jakobson prefaced his comments on specific papers with a general remark mentioning both Saussure and Peirce:

> In the impending task of analyzing and comparing the various semiotic systems, we must remember not only the slogan of F. de Saussure that linguistics is part of the science of signs, but, first and foremost, the life-work of his no less eminent contemporary, Charles Sanders Peirce. Peirce not only stated the need for a semiotic but drafted, moreover, its basic lines. His fundamental ideas and devices in the theory of symbols, and particularly of linguistic symbols, when carefully studied, will be of substantial support for the investigation of language in its relation to other systems of signs (Jakobson, 1971: 555–556).

The key to Jakobson's repeated efforts to combine the Saussurean definition of the sign as the correlative union of the perceptible signifier and the intelligible

signified with Peirce's triadic model of the sign is his idea that meaning is essentially a translation of the sign into another sign. In his many comments on Peirce, Jakobson focused his attention of the triadic division of icon, index, and symbol, which for Peirce involves the complex relationship between sign vehicle and the object referred to, as a way to further distance himself from the Sausssurean notion of the arbitrariness of semiosis in language which, in contrast, deals with unmotivated relationship between sign and meaning, that is, with what Peirce calls the symbol (Jakobson, 1980). Jakobson argued (incorrectly, it turns out) that the Peircean iconic sign is motivated by the similarity of the signifier and the signified, while the Peircean indexical sign is motivated by the contiguity of the signifier and the signified. (Saussure's signified is more accurately equated with Peirce's "immediate interpretant.")

An important next step in synthesizing Jakobson and Peirce was taken in 1976 by Michael Silverstein in a landmark paper that explicitly harnesses the Peircean trichotomy of icon, index, and symbol in order to contrast the decontextualized, referential value of linguistic signs (the subject of Saussurean analysis) with the contextualized, indexical, or pragmatic mode of meaningfulness that operates sometimes independently (e.g., deference forms) and sometimes conjointly with referential functionality (e.g., personal pronouns or other deictic forms or shifters) and is the real key to the linkage between acts of speech and the system of social life. Silverstein sees indexical meaningfulness rather than abstract semantic meaning as the true locus for the modeling power of language in anthropological theory:

> If language is unique in having a true symbolic mode, then obviously other cultural media must be more akin to the combined iconic and indexical modes of meaningfulness. In general, then, we can conclude that "cultural meaning" of behavior is so limited, except for speech, and see a cultural description as a massive, multiply pragmatic description of how the social categories of groups of people are constituted in a criss-crossing, frequently contradictory, ambiguous, and confusing set of pragmatic meanings of many kinds of behavior . . . Culture is, with the exception of a small part of language, but a congeries of iconic-indexical systems of meaningfulness of behavior (Silverstein, 1976: 54).

Having thus distinguished pragmatic or indexical categories and decontextualized or semantic categories, Silverstein proceeds to repeat this distinction at the meta level by separating metasemantics, that is, talk about the semantic code (e.g., glossing), from metapragmatics, talk about the pragmatics of speech. There is a fundamental asymmetry between these two levels: whereas metasemantic discourse is semantic, metapragmatic discourse is never pragmatic in the same sense that the object of that discourse is pragmatic. That is, metapragmatic characterizations never match the function being characterized: while language as a pure referential medium serves as its own metalanguage in metasemantic referential speech events, there can be no metapragmatic speech events in which use of speech in a given functional mode explicates the pragmatic structure of that very functional mode.

Language is the primary vehicle for people to understand the meaningfulness of their social action: it is the dominant expressive means of communication, facilitates the recording of cultural traditions across generations, and performs the metasemiotic function of interpreting other sign systems. But language can also block understanding because speakers regularly misread pragmatic sign relations as semantic ones; and in the course of everyday life they have little awareness of the mediational role language plays in shaping their experience of the world, or they are regularly led to project a cultural ontology out of what Benjamin Lee Whorf called cryptotypic regularities and fashions of speaking. Speakers are also subject to the active regimentation of interpretations by institutionally powerful forces, from schools and the press, to dictionaries and advertising commercials. Silverstein formulates the issue of awareness and lack of awareness in terms of the structural properties of language: "It is very easy to obtain accurate pragmatic information in the form of metapragmatic referential speech for segmental, referential, relatively presupposing indexes. It is extremely difficult, if not impossible, to make a native speaker aware of nonsegmental, nonreferential, relatively creative formal features, which have no metapragmatic reality for him" (Silverstein, 1976: 49). Silverstein's earliest prescription for a Jakobson-inspired *anthropologie sémiotique* in a short paper published in French in 1975 was followed a few years later by his University of Chicago colleague Milton Singer's Distinguished Lecture at American Anthropological Association meetings in 1978, which argued for a Peircean-grounded semiotic anthropology as opposed to a Saussure-inspired semiological approach:

> Without wishing to deny the fruitful ingenuity of a semiological analysis of culture . . . I would urge the application of Peircean semiotic to the problems of culture theory and suggest that we call such explorations "semiotic anthropology." In one important respect, at least, a semiotic theory of signs as a distinct advantage over a semiological theory: it can deal with some of the difficult problems generated by acceptance of the complementarity of cultural and social systems. Because semiology

> limits itself to a theory of signification and linguistic codes, it cannot deal with the problem of how different cultural "languages" are related to empirical objects and egos, to individual actors and groups. The existence of such extralinguistic relations is, of course, recognized by semiologists, but the study of them is relegated to other disciplines – psychology, sociology, economics, geography, and history. They do not enter directly and essentially into semiological analysis. In semiotic anthropology, on the contrary, it is possible to deal with such extralinguistic relations within the framework of semiotic theory, because a semiotic anthropology is a pragmatic anthropology. It contains a theory of how systems of signs are related to their meanings, as well as to the objects designated and to the experience and behavior of the sign users (Singer, 1984: 50).

Following Peirce's key insight that conventional symbols embody iconic and indexical modes of meaningfulness, Singer made a comparative study of emblems of identity such as flags, banners, insignia, and heraldic devices. His ethnographic analysis of emblems in Newburyport, Massachusetts, in the 1970s (a restudy of Lloyd Warner's classic accounts from the 1930s) moved significantly beyond the theoretical positions of both Durkheim and Lévi-Strauss by adopting a semiotic perspective.

> A semiotic analysis of emblems as constructed signs will thus require an understanding of the characters they signify, of the objects they denote, and of the system of conventional signs ("symbols") they use to make statements about the relations of emblems, objects, and characters. Such understandings will be realized in the dialogues between the designers of the emblems (the "utterers") and the viewers (the "interpreters") in the context of ongoing social interactions (Singer, 1984: 108).

Singer uncovered a transformation in the social referents of the indexicality of emblems, from ethnic origin (*Yankee* versus *Ethnic*) to residential duration (*local* versus *outsider*), accomplished by subtle reinterpretation of the latent identities signaled by formally continuous emblems. He witnessed a ceremony rededicating a bronze model (replacing an earlier stolen one) of the 17th century ship *Mary and John* that brought early settlers to the area; this "replica of a replica" was reinterpreted in the 1970s as a symbol of collective identity beyond the lineal descendants of the earliest settlers. Singer also observed the "double or triple symbolism" in multi-ethnic family households, where emblems of identity from different countries of origin are juxtaposed on walls and mantelpieces.

Eric Schwimmer's parallel study of "icons of identity" (1986) among the Orokaiva of Papua New Guinea is a second example of the application of Peircean insights to an ethnographic topic previously treated by Saussurean-structuralist techniques. Whereas Lévi-Strauss' attempt to replace a one-to-one metonymic relationship between social groups and totemic emblems by postulating a formal correlation between groups and totems as two systems of differences, Schwimmer showed that particular plant emblems (*hae*) signal a person's membership in a nuclear social group because an ancestor became spatially attached to that tree (ate it, was born near it, used to sit on it, etc.) and, according to mythological narratives, eventually was transformed into it. So when his descendants use a leaf of that same tree as a trail marker while walking in neighboring territory, they are in fact using a highly informational indexical sign that functions as a nonsemantic icon of group identity. As Schwimmer noted, "It is this shifting back between iconic and indexical that arouses our interest" (Schwimmer, 1986: 373).

A third example of the application of Peircean concepts in ethnographic description is Daniel's path-breaking study of the Tamil culture of India, in which he finds semiotic relations at two levels. The first more encompassing level characterizes the triadic relationship of the ethnographer's understanding (the Sign) representing the informants' culture being studied (the Object), and this necessarily imperfect or aniconic relationship in turn is represented by the resulting ethnographic writing (the Interpretant). (Perhaps a more logical depiction would have the ethnographic writing as the representing Sign, the total fieldwork situation as the Object, and the increased scientific understanding of the culture gained by the community of anthropologists as the Interpretant.) The second level characterizes the multimodal semiotic meanings manifested at various moments in the flux of mundane and ritualized social life.

> Most, if not all signs are mixed. Signs, including symbols (especially symbols), are polysemic . . . Some symbols, especially ritual and religious ones, tend to display their polysemic attributes with far greater élan than do others. The aspect of the sign that I have tried to bring forth is not its polysemy or its multivocality but its polychromy or multimodality. Iconic as well as indexical aspects may be concealed within the same sign. A sign runs in a bundle of cables, so to speak, not in a single strand . . . A satisfactory cultural account must evidence a sensitivity to the multimodality of the signs in that culture, a sensitivity to the significant color that comes to be dominant to those who traffic in these signs in their daily lives, and a sensitivity to the partially or fully concealed modalities that refract the significance emitted by the dominant modal facet (Daniel, 1984: 39–40).

Through close analyses of several interlocking sets of data (including household organization, the

relationship between bodily substance and human action, and pilgrimage rituals) Daniel argues that iconism coding shared substance is the regnant or dominant semiotic style of the culture, in contrast to the pervasive style of symbolization in Western positivist culture (of which Daniel, surprisingly, sees Peirce's semiotic and pragmatist philosophy as representative). It is not accidental, given this postulation of the primacy of iconism in Tamil culture, that the consciousness of pilgrims is described (again using Peircean terminology) as a processual movement from triadic Thirdness to dyadic Secondness to nonanalytical Firstness, this last stage leaving the pilgrim "where there is nothing left to know either through analysis or synthesis. This is *pūrna*, perfect knowledge" (Daniel, 1984: 286).

Indexicality, Mediation, and Ideology

As these and other ethnographic works demonstrate, one of the great merits of a Peircean as opposed to a Saussurean approach to the semiotics of social life is that the category of meaningfulness labeled indexicality, that aspect of sign meaning linked to its context of occurrence, is fully recognized as a mode of signification analytically independent from semantic or symbolic meaning, which depends on decontextualized regularities stipulated by convention. Given that social life is largely concerned with human interaction and the objectification of meaning in material objects, any attempt to analyze the indexical dimensions of culture as if they were purely symbolic, as in the language of flowers or symbols of empire, would be misguided. Indexicality works in two directions, what Silverstein (1976) labels 'presupposing,' signs whose contextual anchor must be known prior to the instance of the sign, and 'creative' or entailing signs whose very occurrence generates the contextual surround in reality or at least in cognitive salience.

Communicative events usually display some sort of construal by participants of the ongoing linguistic and non-linguistic signs – either explicitly in metapragmatic/metasemiotic forms that describe, explain, or even rationalize the signs-in-context, or implicitly in the co-textual organization of the "patterns of emergent entextualization" (Silverstein, 2003: 196). Parallelisms or other kinds of diagrammatic forms that manifest an asymmetrical indexical pattern or moment seem to be widespread semiotic constructs that realize social power in culture (Parmentier, 1997: 37–42). Urban's semiotic analysis of origin myth telling among the Shokleng of Brazil shows this clearly. Origin myths are narrated by knowledgeable men in a highly marked speaking style at death ceremonies, namely, the learning style involving two speakers, one of whom rapidly echoes the individual syllables of the myth uttered by the other. Urban (1985, 1986) argues that, in addition to many dimensions of micro- and macro-parallelism in the myth text, the performance itself is a diagrammatic iconic sign of the production of cultural continuity, a function accomplished by the event itself.

The retrospective interpretation of indexicals in real time can distort their potential for multiple indexical mappings; and asking people after the fact frequently produces interpretations favoring presupposing over creative meanings, the product over the process of production. For example, since product is easier to see than process in the archaeological record, there is a tendency to read material remains in a presupposing rather than creative manner, so that, for example, differential grave goods are said to index degrees of social inequality, thus overlooking the possibility that material elaboration is designed to create an augmented afterlife status. In later reflection, actors tend to re-read indexical multifunctionality, either focusing on the most obvious indexical modality or by translating complex indexicals into decontextualized semantic regularities. Furthermore, multiple indexical meanings frequently piggyback on a single chain of signifiers, whose occurrence can signal spatial, temporal, and social indexicality all at once. And indexical meaning can intersect in complex ways with symbolic meaning, as in the case of duplex signs or shifters, where referential value can only be discovered after indexical calculation.

In order to clear up some confusion in applying analytical labels to processes that operate in distinct yet interlocking levels of semiosis, Elizabeth Mertz and Richard Parmentier (1985) proposed the term "semiotic mediation," based on Peirce's approving citation of the word 'mediation' as a summary description for all semiotic processes at the level of generality or Thirdness (Parmentier, 1985). They identified three levels of semiotic mediation: token mediation, code mediation, and ideological mediation. Token mediation involves the play of sign instances in the give and take of social life, viewed as a flow of signs in context. The circulation of material sign tokens involves various dynamics between the sign values and the social relations they mediate on a continuum ranging from the transactionally generated values of amulets to hoarded noncirculating inalienable possessions. Code mediation deals with the skewing, bias, or refraction that operates between perception and reality, much like a pair of colored glasses modifies sight. Without an alternative or comparative perspective, this mediational effect can easily go unnoticed: members of a society regularly overlook the historical contingency and formal

arbitrariness of their familiar codes, preferring to consider them products of transcendent wisdom or natural order. Cultural codes, like linguistic ones, rarely determine the limits of what can be signaled; rather, they work to facilitate certain expressible meanings, and to prestructure equivalence relations by regular paradigmatic structures and syntagmatic parallelisms.

Ideological mediation has been the subject of much recent research into linguistic and semiotic ideologies, that is, relatively presupposed, systematic sets of assumptions about semiosis in general. Folk ideas about the distinction between natural and conventional signs, notions about the universe as a book, and homologies drawn between linguistic and economic processes are a few examples of widely discussed semiotic ideologies. Analysis of these ideologies is difficult, since it is easy to erroneously substitute a passing articulated expression of an ideology (by a chief, king, or priest, for example) or a spontaneous rationalization prompted by our own metasemiotic inquiry for a truly pervasive, though largely unspoken, semiotic ideology. Semiotic ideologies are also hard to locate given the frequent lack of specific markers for metasemiotic signs in culture. In contrast to the sign processes in social life, artificial semiotic systems (e.g., computer programs) necessarily make a clear distinction between signs operating at a particular discursive level and signs operating at a metadiscursive level with respect to it; the use of markers such as quotations or brackets serves to separate direct signification from comments on the signifying process. In human sign systems, on the other hand, these levels are often formally continuous, with little warning that a shift from use to mention has occurred. Linguistic terms that directly label various dimensions of semiotic functioning, ethnosemiotic labels, can be important clues to the operation of semiotic ideologies, although the ethnographer needs to be careful in not automatically assuming that an elite or specialist vocabulary and awareness reflects the general population.

Under the general rubric of the "semiotics of dominance" Gal (1998) discusses various semiotic processes and devices through which any cultural idea gains the discursive authority to become dominant. A good illustration would be the process Gal calls iconization (relabeled more recently by Irvine [2004: 108] as rhematization) in which the situation in which linguistic features that indexically signal social differentiation is transformed into a situation in which some (iconic) quality of the linguistic feature is represented as parallel to some feature (behavioral, affective, moral) in the social group. Since these devices are accomplished largely through the use of language and since an important subset of cultural ideas includes ideas about language, it follows that these semiotic processes can themselves be the object of debate and contestation. For example, in the late 19th century, Japanese intellectuals and educators identified certain linguistic forms (missing honorifics, phonological contractions of verb endings) in the speech of elite schoolgirls as lazy and vulgar. Their metapragmatic commentaries provided a rationalizing narrative of the origin of these forms in the schoolgirls' connection with impure *geisha* or corrupt Westerners. The commentaries, thus, collapse the temporal and causal relationship of indexicality between the index (the forms) and the indexed (the schoolgirls) into the relationship of iconicity, in which both forms and speakers are simultaneously lazy and vulgar (Inoue, 2004). Herzfeld, similarly, shows how powerful iconicity, or the "illusions of iconic purity," can be as a rhetorical device in the promulgation of nationalist ideologies (1986).

Semiotics of Culture and the Cultural Text

Since the 1970s the so-called Moscow-Tartu School of semiotics has attempted to chart a synthetic theory, combining Saussurean, Peircean, and information-theoretic models, for understanding cultural signs systems, both historically and comparatively. In 1973 a group of scholars associated with this school issued a joint statement outlining a "semiotic-typological" concept of culture that examines both the hierarchically linked semiotic subsystems within a culture and the dynamic opposition of culture and an external, nonsemiotic space of nonculture. The basic unit of analysis is the culture text, which is a functionally integral sequence of signs that carries a coherent meaning.

> From the semiotic point of view culture may be regarded as a hierarchy of particular semiotic systems, as the sum of the texts and the set of functions correlated with them, or as a certain mechanism which generates these texts. If we regard the collective as a more complexly organized individual, culture may be understood by analogy with the individual mechanism of memory as a certain collective mechanism for the storage and processing of information. The semiotic structure of culture and the semiotic structure of memory are functionally uniform phenomena situated on different levels. This proposition does not contradict the dynamism of culture: being in principle the fixation of past experience, it may also appear as a program and as instructions for the creation of new texts (Lotman *et al.*, 1973).

Yuri M. Lotman (1922–1993; 73), the dominant member of the group, argued that the data for cross-cultural comparison are already at the metacultural

level, since each culture displays specific metasemiotic constructs, such as instructional texts stipulating the norms of literary production or the artistic modeling of the universe. Systematic comparison is possible only because of the universal characteristic of cultural texts to be organized in spatial or topological schemes, such as center/periphery oppositions and boundary mechanisms.

The central myth-making mechanism of culture is organized as topological space.

> With projection onto the axis of linear time and from the province of ritual play-action into the sphere of the verbal text, it undergoes important changes: in assuming linearity and discreteness, it acquires the characteristics of a verbal text constructed on the principle of a sentence. In this sense it becomes comparable with the entirely verbal texts arising on the periphery of culture. Yet it is precisely this comparison which makes it possible to discover some very profound differences: the central sphere of culture is constructed on the principle of an integrated structural whole, a sentence; the peripheral sphere is organized as a cumulative chain simply by the accretion of structurally independent entities (Lotman, 1979: 173).

And because every culture, whatever the particular shape of its textual models, understands itself over against nonculture, it is universally the case that culture appears as a hierarchical organization of semiotic codes, including natural languages as well as "secondary modeling systems," that is, complex semiotic languages built upon linguistic materials (Lotman *et al.*, 1973: 76).

From this premise Lotman articulates the general goal of a typological approach to culture. Since the development of metalanguages within different domains or institutions of a culture will not all occur simultaneously, Lotman posits that, from a synchronic point of view, a culture needs to be seen as a cross-section of typologically distinct cultural epochs.

Lotman envisions a type of semiotic consciousness he calls mythological, in which signs (especially proper names) become so indexically linked with referents that the relationship appears asemiotic and thus there can be no hierarchical layering of language and metalanguage. Mythological texts appear to have symbols and metaphors only when translated into nonmythological categories. In the mythic world objects are seen as singular and integral wholes, signs are not ascribed but recognized (being synonymous with proper nouns), word and denotation are identified, and text is isomorphic with the described world, understanding is based on recognition, identification and transformation, and the entire system is monolinguistic.

Lotman's typological approach does not require the unilineal succession of mythological to nonmythological to logicoscientific cultures, but rather speaks of the "prevalence of certain cultural models or of an entire culture's subjective orientation toward them" (Lotman and Uspenskij, 1978: 226). Given the criterion of prevalence, a certain culture can display multiple types of semiotic complexity as a result, for example, of the penetration of mythological features into nonmythological periods (e.g., surrealism or symbolist poetry in 20th century Europe), the differential dynamism of center and periphery in incorporating new semiotic materials, the dialectical tension between motivated symbols and conventional signs corresponding to the opposition between a high sacred level and a low profane level, and the binarism of symbolic activity of state elites and the putatively asemiotic, practical behavior of peasants. In his book *Universe of the mind: a semiotic theory of culture* (1990), Lotman constructs the concept of the semiosphere, by analogy with the biosphere (as coined by the biologist Vernadsky), to refer to the semiotic space that supports all the heterogeneous languages in a culture. "Across any synchronic section of the semiosphere different languages at different stages of development are in conflict, and some texts are immersed in languages not their own, while the codes to decipher them with may be entirely absent" (Lotman, 1990: 126). At the metaphorical center of the semiosphere, Lotman places the most structurally developed languages (including the natural languages of the culture); the peripheral boundary is the locus of innovation and metasemiotic reflection.

The research into the semiotics of culture by Irene Portis-Winner represents the fullest synthesis in contemporary semiotic anthropology of the Moscow-Tartu School, the Prague School, and Peirce.

> Semiotics of culture may . . . be viewed as more encompassing than a general semiotics glottocentrically conceived, since, while it attends to aspects of all sign systems in culture as they interrelate and does not overlook the more abstract level of underlying invariants and codes, it concentrates upon the infinitely variable and endlessly transformable concrete text in culture in relation to its highly variable context, human and nonhuman. The effect of these factors has been to free semiotics of culture from certain limitations historically dominating the broad field of semiotics, namely the emphasis on langue or code to the detriment of parole, and the dominance of the linguistic model in the analysis of all sign systems whether verbal or not (Portis-Winner, 1986: 183).

Based on extensive ethnographic fieldwork both in Slovenia and among Slovenes in the Cleveland, Ohio, area (1973–1995), Portis-Winner finds that a subset

of cultural texts (as defined by Lotman) dealing with ethnic groups, relations, and boundaries display two correlated levels of dualism. First, these ethnic cultural texts are dualistic in that the unique characteristics of a particular ethnic group are highlighted in opposition to the characteristics of other groups; second, ethnic cultural texts are dualistic in the two ways in that they represent ethnicity, implicit montage and explicit montage, concepts drawn from Lotman's work on the semiotics of cinema. Portis-Winner generalizes the distinction between implicit montage, which involves the reorganization and transformation of images from the same semantic field, and explicit montage, which involves the juxtaposition of elements from different semantic domains and, by extension, the crossing of narrative boundaries. She then shows how one item, the *kosolec* (a large wooden hay rack in farmers' fields in Slovenia), can be an ethnic cultural text in both implicit and explicit senses:

> In the new ethnic culture the kosolec takes on various forms, such as a toy, a small carved trinket, or a landmark in the Cleveland farmlands. Here the compared elements, the different manifestations of the kosolec, form implicit montages, taking their origin from one semantic domain but inducing abstract, associative meanings as a set. Recollections of village activities, threshing, hay rides, and landmarks, are all brought together by the modality of the changing shapes of the kosolec. On the other hand, when the kosolec is covered with hay and juxtaposed to a truck on which it rides in a Fourth of July parade down Main Street in Cleveland, carrying a sign inscribed in large letters with the words "heartland of Slovenia," the kosolec suggests an explicit montage, namely the juxtaposition of elements from very different domains (Portis-Winner, 2002: 58).

Ethnic cultural texts (of either type) produced in a diasporic community can depict the origin village as timeless or mythological, enabling individuals who return for visits to overlook social changes; and in certain festive contexts ethnic cultural texts can represent ethnic realities as liminal or even carnivalesque. The influence of Peirce appears in Portis-Winner's use of semiotic portraits of three generations of related informants from both Slovenia and Cleveland to construct an extended human sign, a concept that expands on Peirce's discussion of the parallelism between a 'man' and a 'word' and treats the individuals in these portraits as boundary-crossers, equivalent to the culture heroes in Lotman's narrative analyses.

Semiotics and Material Culture

If one of the advantages of a Peircean approach in semiotic anthropology is that its model of meaningfulness encompasses but is not based on language, then there will be obvious benefits for the ethnographic and archaeological study of material objects considered, as Vološinov suggested, as simultaneously things and signs. Certainly Peirce's concepts of indexicality (grounded in spatiotemporal contiguity) and iconicity (grounded in formal resemblance) would be essential to this project (Keane, 2003: 415–417). And his distinction between individually occurring signs (sinsigns) and instances of general regularities (tokens of types) immediately raises important methodological questions. Given the obvious role that material objects play in mediating individual and group relations, as trade goods and exchange valuables, for example, and as repositories of sedimented cultural values and historical experiences, Peirce's model of the sign is directly applicable to many ethnographic cases. Peirce's inclusion of the Intepretant as a fundamental constituent of the sign relation, however, presents difficulties for archaeologist working without living informants, textual evidence, or possible ethnographic analogies. The relative permanence of material objects results in multiple layers of Interpretants: users of objects who are contemporaneous with their production regard them differently than people reacting to them centuries later, and scholars treating objects as evidence of stylistic growth or of evolutionary development construct radically different Interpretants than either of these two (Parmentier, 1997: 51).

On the other hand, a Saussurean effort to talk about the material world as directly meaningful has occasionally assumed a full or partial analogy between language and objects; the material record is analyzed in terms of grammar, speech acts, constitutive rules, denotation/connotation, and textuality. Several criticisms of this language analogy need to be made, including the absence of evidence that objects have the degree of relative arbitrariness found in linguistic symbols, that the meaningfulness of objects displays the double articulation found in all languages, and that the systematicity of patterning in the material record is driven by decontextualized referentiality. But the Saussurean concept of value as the positional meaning of a sign can play a positive analytical role, especially in situations where multiple objects display variation in quality aligning with differentiated spatial arrangement (Herzfeld, 1992) or with a calculus of relative exchange value (Keane, 1997: 72–75; Munn, 1983: 302).

Semiotics and Diachrony

Peirce and Saussure have had only a modest impact on diachronic or historical work in semiotic

anthropology. Marshall Sahlins, in charting new territory for a structural history based on the repudiation of the ahistorical disposition of classic structuralist theory (such as the notion of stereotypic reproduction), sees two critical dilemmas in the Saussurean project of general semiology (1995: 246): first, that the systematicity of signs requires that individual signs have no externally generated values (since their value is entirely positional) and, second, that the collective or social dimension of sign systems necessitates a strict separation of the system of signs from the implementation of sign tokens in discourse and interaction. Rather than throw away a valuable Saussurean insight, that "cultural categories by which experience is constituted do not follow directly from the world, but from their differential relations within a symbolic scheme" (Sahlins, 1985: 147), Sahlins attempts its recuperation by demonstrating the role of events in revaluing signs, especially through the indexical relations between signs and their real-world objects in which "signs are set in various and contingent relationships according to people's instrumental purposes – purposes of course that are socially constituted even as they may be individually variable" (Sahlins, 1981: 5). Social praxis puts symbolic systems in jeopardy, since the instantiation of cultural categories in social action implies the functional revaluation of signs: "No longer a disembodied or virtual semiotic system, meaning is now in contact with the original human powers of its creation ... In action signs are subsumed in various logical operations, such as metaphor and analogy, intensional and extensional redefinitions, specializations of meaning or generalization, displacements or substitutions, not to neglect creative 'misunderstandings'" (Sahlins, 1975: 151). In his extensive comparative research on Polynesian cultures, and especially in his reconstruction of the cultural impact of Captain James Cook's death in the Hawaiian Islands in 1779, Sahlins documents the performative quality of Hawaiian history.

> The Hawaiian order is more active historically, in a double way. Responding to the shifting conditions of its existence – as of, say, production, population, or power – the cultural order reproduces itself in and as change. Its stability is a volatile history of the changing fortunes of persons and groups. But then, it is more likely to change as it so reproduces itself (Sahlins, 1995: 250).

In a series of ethnographic studies dealing with Palau or Belau (Micronesia), Richard Parmentier develops two semiotic angles implicit in Sahlins' theory of structural history. First, he finds deployed in origin myths and historical narratives a set of spatial models found in various contexts in the culture. These models are diagrammatic icons in Peirce's terminology, that is, complex signs that represent the relations among parts of some object by analogous relations among components of the sign vehicle. In Palau these ethnosemiotic schemata include the model of the 'path' (*rael*), persons or objects moving or lined up in a linear order from a starting point to an ending point; 'cornerposts' (*saus*), four coordinated elements supporting a quadripartite structure; 'sides' (*bitang*), an oppositional pair of elements in which both halves are identical yet inverse; and 'larger/smaller' (*klou/kekere*), a continuum of elements in a series ranked according to the degree or strength of a single dimension such as social rank, wealth, physical maturity, or sacredness.

In contrast to a simple structuralist account, Parmentier argues that the narrative use of these four models in the present-day storytelling represents the history of the society as the logical unfolding of three of these models, that is, as the development of political organization from paths to cornerposts to sides. This sequence does not represent the actual development of Palauan society, as might be uncovered in archaeological research, but rather expresses a cultural logic grounded in the meanings of the semiotic models themselves: 'paths' imply the fundamental act of creating cultural meaning as the categorization of instances as tokens of general types, 'cornerposts' express the hierarchically graded and functionally differentiated order found in mature or stable cultural institutions; and 'sides' codes oppositional, complementary, factional, or competitive units that presuppose a dyadic structure as a balanced whole. Whereas Sahlins concentrates on the revaluation or realignment of cultural values (male/female, chief/commoner, warfare/agriculture, foreign/indigenous) as a result of the engagement of these values in social action (especially in situations of culture contact), Parmentier focuses on the recategorization of cultural values in the rhetorical deployment of semiotic models that have a relatively constant meaning.

Second, Parmentier documents a particular category of historicizing signs in Palauan culture called *olangch*, meaning 'commemorative or historical marker.' These markers, including for example personal names and titles, gravestones and anthropomorphic stones, exchange valuables and money, ritual prerogatives and social routines, function as cultural shifters by articulating the organizational diagrams in contexts of social action and experience. *Olangch* are permanent signs that are present evidence of a significant past, but having been created in certain contexts in the past they continue to undergo strategic manipulation in the present. Parmentier divides the functioning of these indexical symbols into "signs of history" and "signs in history": signs of history

represent the past as history in the sense of providing an explicit classification in terms of the four differentially valued diagrammatic schemata; signs in history are signs of history that, additionally, become objects of social interest and action because of their value as reified embodiments of historicity: "olangch look in these two directions, toward the typifying role of schemata and toward the sedimenting role of practice" (Parmentier, 1987: 308).

Semiotics of Architecture

P Pellegrino, University of Geneva, Geneva, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Two definitions of architecture are conceivable: the one from the architect, for whom the architecture is the conception of a measured structure inscribed in a *monument*, a conception appealing to models and rules of composition, to a knowledge transmitted by masters; and the other from receivers of the architectural project, clients and users, for whom an architecture is a building in its material reality, an *instrument* (Prieto, 1975) with functions, endowed with usefulness, which corresponds to needs of spaces and conforms to usages determined by a social system.

These two definitions bear therefore on two different objects, a knowledge applied in a project for the first, an instrument responding to needs for the second. They are complete only if the first includes the second, if the conception of the architect takes for a goal the needs of the users of the building in project, and reciprocally if the second seizes the first, if needs of users are open to possibilities provided by instruments projected by the architect (Pellegrino, 2003). This creates problems of conception as much as of reception, that is to say semiotic problems of communication.

Summing up modern architects' attempts to define functions (Le Corbusier, 1930), Umberto Eco proposes to differentiate them in *first*, denoted functions, which articulate the building to a usage, and *second*, connoted functions which articulate it to distinctive values of cultural systems; the emergence of events crossing these systems continually displaces objects of usage between first functions and second functions (Eco, 1968).

The physical instrument conformation remaining stable, the cultural process confers upon it a new signified in a consumption of forms and an obsolescence of values. Signifier forms are recuperated and endowed with other signifieds. With regard to the architecture, the physical stability refers to stability of places that buildings occupy and of spaces that they offer for usage.

This stability testifies to a state of the distribution of the signifiers and, at the zero degree of the marking of the space, fixes the empty place of the signified (Barthes, 1967). The signifiers are understood as such

Semiotics of Architecture

P Pellegrino, University of Geneva, Geneva, Switzerland

© 2006 Elsevier Ltd. All rights reserved.

Two definitions of architecture are conceivable: the one from the architect, for whom the architecture is the conception of a measured structure inscribed in a *monument*, a conception appealing to models and rules of composition, to a knowledge transmitted by masters; and the other from receivers of the architectural project, clients and users, for whom an architecture is a building in its material reality, an *instrument* (Prieto, 1975) with functions, endowed with usefulness, which corresponds to needs of spaces and conforms to usages determined by a social system.

These two definitions bear therefore on two different objects, a knowledge applied in a project for the first, an instrument responding to needs for the second. They are complete only if the first includes the second, if the conception of the architect takes for a goal the needs of the users of the building in project, and reciprocally if the second seizes the first, if needs of users are open to possibilities provided by instruments projected by the architect (Pellegrino, 2003). This creates problems of conception as much as of reception, that is to say semiotic problems of communication.

Summing up modern architects' attempts to define functions (Le Corbusier, 1930), Umberto Eco proposes to differentiate them in *first*, denoted functions, which articulate the building to a usage, and *second*, connoted functions which articulate it to distinctive values of cultural systems; the emergence of events crossing these systems continually displaces objects of usage between first functions and second functions (Eco, 1968).

The physical instrument conformation remaining stable, the cultural process confers upon it a new signified in a consumption of forms and an obsolescence of values. Signifier forms are recuperated and endowed with other signifieds. With regard to the architecture, the physical stability refers to stability of places that buildings occupy and of spaces that they offer for usage.

This stability testifies to a state of the distribution of the signifiers and, at the zero degree of the marking of the space, fixes the empty place of the signified (Barthes, 1967). The signifiers are understood as such

more by their correlative positions than by their contents; they carry in an intrinsic manner a value by offering a place for a possible signified.

But the signifier and the signified do not correspond according to a permanent norm, as is the case in the constitution of a lexicon; there is an open gap between signifier forms and the forms of what is signified, a gap that precisely is where the work of the architect enters. This gap renders codes, according to what are defined as the second and first functions, **variable** and **opened**. Changing, the coded signifieds do not refer in a one-to-one manner to stable signifiers.

One may wonder how this stability of the conformation of the signifiers remains, while that of the signifieds changes, as the first and second functions displace; how, for example, an archeologist architect can determine the form of a crumbled building from incomplete fragments while not knowing the precise location and the usage of origin.

In this case it is necessary to admit that architectural codes are constitutive without being directly linked to functions (firsts and seconds) admitted by the usage; that there is a cultural autonomy of the architecture, that the architectural conception is self-referential. The work is generated by detaching itself from instrumental codes admitted by the usage; the architecture escapes from determination by functions.

The self-reference of the work, however, draws in relations of homology, in a similar structural diagram governing plans of the expression and plans of the content of the architecture, as in an idiolectal code (Eco, 1968). But this homology is arbitrary; it is the fruit of an intention, the object of the project of the architect, and the partitions of the content proposed by the architectural plan are not necessarily recognized and resumed by the usage of the building.

Even if, as instrument, in its internal functioning, it maintain causal **necessary** relations between its parts (Alberti, 1485), the architectural building renders possible, but not obligatory, operations feasible in its usage; projected by the architect, the shelter communicates its function of protected internal space as a possible but not necessary function. The architect therefore asserts its autonomy in the face of the virtuality of usages of its works. He defines the autonomy of its work not by a servile following of the habits and desires of users of its products, but in reference to other works that it accepts as models; models that give it measured rules of spaces that it projects, forms and forces to postpone in the drawing of its projects. To assert the autonomy of its conception, the architect interprets the expectations of addressees of its work, and classifies it according to types (Levy, 2003), but gives them a reply that is based on the logic of the models of a learned architecture.

From the most ancient treatise that has reached us, the *Ten books of architecture* of Vitruvius, we learn that this science is acquired by practice and by theory (Vitruvius, circa 80 B.C.). The practice comprises the execution of designs whereby the matter of architectural works is given suitable form. The theory explains and demonstrates the fitness of the proportions of the things proposes to make, the relevance of the measurements given to the various parts of the edifice planned. Architecture cannot do without either its theory or its practice.

And theory in architecture, according to Vitruvius, is a semiotic theory, inasmuch as in architecture, as in any other science, two things are noticed: that which is signified and that which signifies. Still more precisely, it is a theory based both:

> on a **metasemiotic** system, in which the thing signified, the thing stated and spoken about, is the object of the architectural design, the building, a tool possessing a certain utility for those who use it;
>
> and on a **connotative** representation, in which the thing that signifies in the design of the object of architectural project is the demonstration given of it by reasoning, supported by science.

For Vitruvius, what signifies in architecture is not the building *per se* but the secondary connotative signification that architecture gives of the connection that the edifice may have with things other than itself: certain items of knowledge, a branch of learning. In architecture, the **demonstration** of the usefulness of the instrument is given by a measured design that connotes a reasoning (Table 1).

We also learn that architecture *is a science that should be accompanied by a great variety of studies and knowledge, by means of which it judges all works of the other arts that belong to it*: to the point where *most cannot comprehend that the understanding and memory of one man should be capable of so much knowledge*. All sciences, however, have *a communication and link between them*; *universal science is composed of all these sciences*, so that it is enough for the

Table 1

Signifier 1 reasoning	Signified 1 reasoning	
Signifier 2 design of the reasoning		Signified 2 **connotation** of the reasoning
Signifier 2 design of the building		Signified 2 **metasemiosis** of the building
	Signifier 1 building	Signified 1 building

architect to know the *consistencies . . . between certain things that are common to all the sciences, one of which helps in learning another more easily.*

The connotative connection between what architectural reasoning signifies and what is signified in the design of the edifice that it builds is thus marked in the building as a *right measurement* of objects *in relation to their use*; architecture is then *constituted* by operations of measurement, as disposition and distribution, as well as the ordering, rhythm, and proportion of the parts of the edifice. And the theory of architecture is a theory of measurement (Boudon, 1975) signified in the edifices it produces.

As an instrument endowed with a usefulness, the building is the semiotic object of a demonstrative metadiscourse explaining intentions that preside over partitions of which it is the object and to the articulation of the variable forms of its content and its expression. This metadiscourse is contained in the forms of the project; it disarticulates and rearticulates its models of reference, to seize its deep semantic and to neutralize its context, as it decomposes and recomposes its in a graphic reasoning (Figure 1) by putting them at stake to test its syntactic rules and transform the context in a measured co-text (Jeanneret, 2005).

Figure 1 Sketches of the House VI, P. Eisenman, Cornwall, 1972–1973. (Source: P. Eisenman, 1987, *Houses of cards*, Oxford University Press, New York, with permission.)

By defining itself arbitrarily in an articulation of components of the graphic sign that its drawing handles between metalanguage and connotation, the plan of the architectural expression creates a connotative articulation between expression and content; thus, by the ambiguity and the contradiction (Venturi, 1966) between its levels of shape, architecture escapes habit, escapes from the reproduction of usage norms and the imitation of a stylistic manner.

As monument, the building is the semiotic object of connotation. The shape taken by the signifier enters into measured relation with that taken by the signified (Pellegrino, 2004). It represents the communication of a primary conception with which a secondary, sometimes contradictory one is brought into relation, and interprets its functioning as a measuring of an articulation (Table 2).

It is then the articulation of the design by the measuring, presenting itself as a monument, a mechanism of communication that gives meaning to the form of the expression as well as to the form of the content. The intention of the architect is thus measured in a design that contains and expresses it.

Exploiting this articulation, in opposition to the concept of form of the modernist architects, for whom **form follows function** (Sullivan, 1903), contemporary architects develop an articulation of **complex form**, that is to say of form conceived at several levels of design (Muntañola, 1996).

To seize these levels of complexity, A. Colquhoun draws attention to the concept of *figure* (Colquhoun, 1981), which stems from the classical tradition of rhetoric (Fontanier, 1830). The figure is built upon a procedure of secondariness and is designed to persuade the receivers of the values to be adopted.

But form is conceived as an approximation as faithful as possible to the referred content, which **remains unutterable**, i.e., to the signified of the second level of conception (Table 3). At the first level, the form is conceived in an articulation inserted into a system of potentialities; it may be symbolized and enter into

substitutive paradigms, for example that of orders of columnage.

The connotation diagram is then as in Table 3, where the form of the first level of conception is inserted in a constituted culture, a learned one in this case; whereas at the second level, it tends to inform an unknown, x, which is the interpretation of its use. Thus contemporary architects propose to reinsert the figure in the conception of their project, but at the same time creating shocks and fragmenting it (Figure 2).

No longer seeking to produce functional form, they also tend not to *integrate fragments in a coherent system of the figure* (Colquhoun, 1981) but, by playing on connections, to juxtapose figurative elements in an unexpected manner producing the meaning of the measure (Table 4).

We may ask, then, whether what links the fragmentary references one to another is the fact that they interpret certain attributes of the second-level signifier. Rhetoric helps us to find the answer (Perelman, 1989); it is a logic of the figure in which attributes maintain measured relations with what they connote: synecdochic relation, correspondence of the part with the whole; relation of metonymy, connection of the container to the content; contrastive relation, of a part antithetical to the whole that posits it; relation of semantic metaphor, resemblance that posits a gap

Table 4

in order to propose its reduction (Ricoeur, 1975); relation of catachresis, to extend the meaning of a part to a whole that no longer has any meaning; relation of integrative analogy, in which the parts maintain with one another relations similar to the relations that the totality they constitute maintains with another totality (Quatremère de Quincy, 1823). In these figures, the connotative drift opens a gap, a reduction of the primary signifier to a few of its attributes, to reveal a secondary signified that restores meaning to the complexity of a whole. And this rhetoric of the project does not remain with the surface of forms, but acts at the depth of their genesis to introduce there, by displacement, subtraction, and addition, spatial measured components of a monument previously ignored.

Semiotics: History

J Deely, University of St Thomas, Houston, Texas, USA

© 2006 Elsevier Ltd. All rights reserved.

Semiotics is the body of knowledge that arises from thematic or systematized study of the action of signs, called 'semiosis,' wherever that action occurs in the universe. If, as has been suggested in the Kassel symposium opening the 21st century discussion of semiosis as the subject matter of semiotic inquiry (Nöth, 2001; see also Deely, 1996), the action of signs is coextensive with the physical universe itself, then the history of *semiosis* itself would be nothing less nor other than the history of what has heretofore been called 'evolution.' Be that as it may, the history of *semiotics* is quite another matter, for here we are studying directly not the *action* of signs in the world of nature or culture, but only the *awareness* of that action insofar as it enters into that systematic body of knowledge called 'semiotics.'

The thinkers of the Latin Age, inspired by Aristotle, liked to distinguish between remote and proximate potentialities. Thus, awareness or knowledge of the action of signs was no more than a remote possibility in the long ages of cosmic semiosis (or evolution) that preceded the establishment of those forms that we call 'conscious life,' the animals. Even among the animals, however, prior to the human animal, called by Aristotle ζῳον λογον ἐχῶν and by the Latins *animal rationale*, semiotics remained a remote possibility, not a proximate one. For the precursors of human beings in the biological community, the ζῳα λογον ουκἐχῶν or 'nonlinguistic animals' of Aristotle, the *animalia bruta* of the Latins, make use of signs but without knowing that there are signs. Zoösemiosis, the action of signs in and among animals, gives rise to zoösemiotics only within anthroposemiosis, the human use of signs, not within zoösemiosis as such.

So the actual or proximate possibility of semiotics as a distinctive branch or field of knowledge comes to be only with the emergence on earth of animals capable not just of using signs but also of knowing that there are signs. These animals, originally called, as we have noted, ζῳα λογον ἐχῶν in philosophy, later *animalia rationalia* or 'rational animals,' were also the bearers of the proximate possibility of developing semiotics as a distinctive kind of knowledge. From this point of view, on Aristotle's own terms that a thing is best known from what it finally becomes, the ζῳον λογον ἐχῶν is best described not in terms of its subjective constitution of possibility as a 'rational animal,' or even as a 'thinking thing' (*res cogitans*, as modernity would conceive it), but in terms of what is most distinctive about the exercise of awareness in such an animal as expressing not only its animality but also its ties to the larger world of nature, inorganic as well as organic. So the richest definition of the human being as ζῳον λογον ἐχῶν is the *semiotic animal* (Deely, 2002, 2003). And the history of semiotics is the history of the development of the awareness among human beings *that there are signs* distinct alike from objects and things to the realization that signs in their proper being are invisible to sense and presupposed in their action both to the constitution of objects and the exploration of things.

In fact, the three main definitions philosophy has given of the human being – ζῳον λογον ἐχῶν in the Greek period, *animal rationale* in the Latin Age, and 'semiotic animal' today – correspond to the three main stages in the development of semiotic consciousness, as follows. The *presemiotic stage* begins with the appearance of human beings as the original animals capable of knowing that there are signs, preliminary to realizing that capacity in various theoretical fashions. The *protosemiotic stage* begins with the first proposal of sign as a general mode of being transcending nature and culture, inner and outer of consciousness, in the age of Augustine. Semiotics: History

J Deely, University of St Thomas, Houston, Texas, USA

Semiotics is the body of knowledge that arises from thematic or systematized study of the action of signs, called 'semiosis,' wherever that action occurs in the universe. If, as has been suggested in the Kassel symposium opening the 21st century discussion of semiosis as the subject matter of semiotic inquiry (Nöth, 2001; see also Deely, 1996), the action of signs is coextensive with the physical universe itself, then the history of *semiosis* itself would be nothing less nor other than the history of what has heretofore been called 'evolution.' Be that as it may, the history of *semiotics* is quite another matter, for here we are studying directly not the *action* of signs in the world of nature or culture, but only the *awareness* of that action insofar as it enters into that systematic body of knowledge called 'semiotics.'

The thinkers of the Latin Age, inspired by Aristotle, liked to distinguish between remote and proximate potentialities. Thus, awareness or knowledge of the action of signs was no more than a remote possibility in the long ages of cosmic semiosis (or evolution) that preceded the establishment of those forms that we call 'conscious life,' the animals. Even among the animals, however, prior to the human animal, called by Aristotle ζῳον λογον ἐχῶν and by the Latins *animal rationale*, semiotics remained a remote possibility, not a proximate one. For the precursors of human beings in the biological community, the ζῳα λογον ουκἐχῶν or 'nonlinguistic animals' of Aristotle, the *animalia bruta* of the Latins, make use of signs but without knowing that there are signs. Zoösemiosis, the action of signs in and among animals, gives rise to zoösemiotics only within anthroposemiosis, the human use of signs, not within zoösemiosis as such.

So the actual or proximate possibility of semiotics as a distinctive branch or field of knowledge comes to be only with the emergence on earth of animals capable not just of using signs but also of knowing that there are signs. These animals, originally called, as we have noted, ζῳα λογον ἐχῶν in philosophy, later *animalia rationalia* or 'rational animals,' were also the bearers of the proximate possibility of developing semiotics as a distinctive kind of knowledge. From this point of view, on Aristotle's own terms that a thing is best known from what it finally becomes, the ζῳον λογον ἐχῶν is best described not in terms of its subjective constitution of possibility as a 'rational animal,' or even as a 'thinking thing' (*res cogitans*, as modernity would conceive it), but in terms of what is most distinctive about the exercise of awareness in such an animal as expressing not only its animality but also its ties to the larger world of nature, inorganic as well as organic. So the richest definition of the human being as ζῳον λογον ἐχῶν is the *semiotic animal* (Deely, 2002, 2003). And the history of semiotics is the history of the development of the awareness among human beings *that there are signs* distinct alike from objects and things to the realization that signs in their proper being are invisible to sense and presupposed in their action both to the constitution of objects and the exploration of things.

In fact, the three main definitions philosophy has given of the human being – ζῳον λογον ἐχῶν in the Greek period, *animal rationale* in the Latin Age, and 'semiotic animal' today – correspond to the three main stages in the development of semiotic consciousness, as follows. The *presemiotic stage* begins with the appearance of human beings as the original animals capable of knowing that there are signs, preliminary to realizing that capacity in various theoretical fashions. The *protosemiotic stage* begins with the first proposal of sign as a general mode of being transcending nature and culture, inner and outer of consciousness, in the age of Augustine. And finally, the stage of *semiotics proper* begins as a proximate possibility with the establishment theoretically in the work first of Poinsot and next of Peirce of how it is that the being proper to signs transcends, or, in a certain way, 'maintains an indifference to,' the

modern division of philosophers into 'realists' and 'idealists.'

According to this way of considering the matter, the modern period itself, wherein the ζῳον λογον ἐχῶν is conceived solipsistically as a *res cogitans*, appears as a 'cryptosemiotic interlude' between the original vindication of semiotic consciousness in the 17th century work of John Poinsot and resumption of the development of that consciousness in the late 19th–early 20th century work of Charles Sanders Peirce. Peirce stands historically as last of the moderns who is also first of the postmoderns in the matter of semiotics proper, just as his predecessor, John Poinsot, can rightly be termed the last of the medievals who is first of the postmoderns in this same matter of semiotics proper. Poinsot and Peirce, across the centuries separating the Latin Age from postmodern times in intellectual culture, stand shoulder-to-shoulder – indeed, joined at the hip – as the initiators of the postmodern philosophical epoch, inasmuch as both alike are the first among the giants of thought thematically to recognize and systematically to establish the parameters of the Way of Signs, the path leading "everywhere in nature, including those domains where humans have never set foot" (Emmeche, 1994: 126). It is to the understanding of this path that semiotics gives us the means integrally to aspire. We are at the nexus and *initium* of postmodernity.

Now the notion of 'cryptosemiotics' and 'cryptosemioticians' should be an incidental or marginal category, but it is not. Cryptosemiotics is a category made necessary in the main by an historical accident. After – and (as I think) largely as a result of – the disastrous condemnation of the view of Galileo and Copernicus concerning the relative motion of sun and earth as a heresy contrary to the Word of God, philosophy in the 17th century deviated from the Way of Signs, reached at the end of the arduous protosemiotic development, unto the Way of Ideas. The Way of Ideas effectively concealed the requirements of semiosis respecting the interconnections between objects and things in favor of a path that could only lead the human mind ever deeper into the labyrinth of its own constructions in isolation from any recognizable contact with the independent realm of nature. An independent realm of nature is what the medievals called *ens reale*, and what philosophy in ancient Greece had begun by awakening the ζῳον λογον ἐχῶν to under the guise of ον or 'being' as that which can only be 'said in many ways' (το ὀν λ∈γ∈ ται πολλαχως), including first of all 'independently of the finite mind.' The modern period of 'epistemology in philosophy,' in short, missed the point of the dependence of human knowledge throughout on the action of signs, semiosis. This is the action that alone makes a world of objects, or 'Umwelt,' possible in the first place for any animals. The horror inspired by the fate of Galileo inspired thinkers of the modern formative years to take all too seriously the warning of Descartes (1628: 13) that "there is a considerable danger that if we study these works" of the Latin scholastics "too closely traces of their errors will infect us and cling to us against our will and despite our precautions." Thus, was the vantage proper to semiotics hardwon between Augustine and Poinsot lost to the modern centuries.

So, just as after Augustine 397 A.D. there could hardly be any more simple 'presemioticians,' so after the publication of Poinsot's *Tractatus de Signis* in 1632 there will only be possible, in this matter of the history of semiotics, *cryptosemioticians*, on the one hand, or, on the other hand, semioticians proper. Cryptosemioticians are thinkers who should have been semioticians and would have been but for ignorance – ignorance *either* of the medieval Latin development (the case of modern philosophy); *or* of the central thrust of the postmodern Peircean development; *or*, more commonly on the contemporary scene (Sebeok, 1971, 1977; Deely, 1986b, 2001: ch. 16, 2003b, 2004; Deely *et al.*, 1986: viii–xvii), *of both*, as in the case of Ferdinand de Saussure (1916) and the 'limiting development of semiology.' By contrast, *semioticians properly so-called* (or 'semiotists,' as Rauch, 1983: 3 would have it, for 'anyone who explicitly does semiotics') will be those who undertake the study of signs not unwittingly or indirectly but explicitly in the recognition of treating a distinctive mode of being with a consequently distinctive sort of action operative no less in nature than in culture and in the interweaving of the two we call 'experience.' Of course, a true semiotist might emerge ignorant of his forebears, as the lad in the 1800s who discovered on his own the calculus of Leibniz and Newton. But the late modern network of global communications renders this prospect increasingly unlikely, even as the cryptosemioticians are a dying breed in the wake of the 20th century rediscovery and seminal development anew of semiotic consciousness.

There we have, then, the main divisions for our consideration of the history of semiotics: presemiotics, protosemiotics, and semiotics proper (the postmodern development), wherein begins to be developed in earnest the consequences of Roger Bacon's suggestion and Poinsot's establishment of the being of sign as consisting in triadic relation.

Presemiotics

Let us try to imagine the situation of truly primitive human beings. I mean the really early human beings

prior even to the evidence for the civilizations of Sumeria, Egypt, Babylonia, Assyria, Persia, India, and China. That evidence carries us backward only 7000 years or so from our 2005 A.D. No one knows how long has the animal called by Aristotle *ζῳον λογον ἐχων* prowled this earth, though the best guesses approximate or exceed one million years (sometimes by a factor of fifty!). No matter how we approach this animal, it differs from the other animals (originally, presumably, even from both members of the first pair to engender or parent it) in the way that a pregnant woman differs from a woman who is not pregnant – that is to say, by a factor that admits no middle ground, even though, *once given*, it admits of degrees of development. As an animal, this creature perforce possessed the capacity for sensation, for so interacting with its environment as to *become aware* of certain aspects or features of that environment. As a so-called 'higher animal,' an animal not only able to become partially aware of its surroundings but further to fashion that awareness into a world of objects perceived as to be sought (+), avoided (−), or safely ignored (∅), our *ζῳον λογον ἐχων* possessed interior senses as well as the so-called external ones (cf. Deely, 1971). Hence, it could model the world for the purposes of its own interests and survival – could fashion, as we say in semiotics today, an 'objective world,' or Umwelt (Kull, 2001), in contrast to the mere physical environment in its being indifferent to the interests of the animal foraging within it.

But this animal Umwelt as such knows no difference between objects and things. True, in sensation the two are aspectually identified, and this aspectual identification is incorporated within the perception of animals to constitute their irreducibly 'realistic' orientation. But the 'realism' of *ζῳα λογον ουκ ἐχῶν* is not and cannot be the same as the 'realism' philosophy seeks to vindicate among humans. For the realism of animals extends no further than the objective world *in its very objectivity*, that is to say, in its relations as such to the animal cognizing and cathecting.

Enter the *ζῳον λογον ἐχων*

The animal world of the *ζῳον λογον ἐχων*, by contrast with the Umwelt of all its predecessors among the animals *λογον ουκ ἐχων*, includes a further dimension. For whereas all the objects of animal perception without exception relate to the animal as +, −, or ∅, the *λογον* of the *ζῳον λογον ἐχων* adds to this perception a further relation of the Umwelt as a whole *to itself*. This relation is not, as a relation, 'real' outside of and apart from the awareness of the *ζῳον λογον ἐχων* perceiving. But this relation is nonetheless sufficient to sever the exclusive 'self-interest' set of relations of the objective world to the biological nature of the animal perceiving that world. The *λογον*, so to speak, exactly as Sebeok (1984, 1986, 1987, 1987a) was the first in semiotics to point out, drives a wedge between the self-interest of the animal in the objects of its awareness as +, −, or ∅, and the possible *further* awareness of those same objects as somehow existing in their own right *whatever the interested awareness of the animal perception*. This added awareness is what Aristotle called simply a grasp of *ον*, and Thomas Aquinas (followed in this detail by Duns Scotus) more fully termed *ens primum cognitum*, the species-specifically distinctive element of human awareness present in all the awareness of *ζῳον λογον ἐχων* as such, perceptual and sensory as well as intellectual, but owing originally to the *λογον*, the 'intellectual' element (and hence absent entirely in the *ζῳα* lacking *λογον*). We could say, using a metaphor to express a truth considerably more than metaphorical, that the awareness of the *ζῳον λογον ἐχων* is pregnant with an understanding of being (which will prove to require expression 'in many ways' – *πλεοναχως λεγεσθαι*) that is completely impossible for the *ζῳα λογον ουκ ἐχων*.

Now, for the first time, there stalks the earth a *ζῳον* that sees first of all not merely a world of objects to be dealt with but a world of things existing. Signs as such have barely entered the picture, but they are already everywhere, as we shall come to see.

Signs in the World of the *ζῳον λογον ουκ ἐχων*

Remember our perspective: we are trying to rethink or imagine the situation of the *ζῳον λογον ἐχων* newly born on earth, making its way toward a fuller and fuller understanding of its species-specifically distinctive awareness of the objective world as a realm of being over and above, above and beyond, the zoösemiotic character of that world as an Umwelt of safe (+), dangerous (−), and neutral (∅) places to roam. It is easy enough to see that such a world is a world permeated with signs, and fallible signs at that. For if one animal never mistook the objects 'safe to ignore,' they would never fall prey to the other animals seeking and needing them for food. The world is a dangerous place, and the animal who cannot rightly 'read the signs' distinguishing the safe from the dangerous is not long for this world. But what are these signs which it reads? For the animal *λογον ουκ ἐχων*, the 'brute animal' (as the medieval Latins put it), signs are nothing more than a particular class or aspect of objects not even recognized as such, but simply as sense-perceived objects presenting what is to be sought or avoided in the vicinity, period. Full stop.

So it is no wonder, and indeed to be expected, that the *ζῳον λογον ἐχων*, making its way among the plants and streams, hills, mountains, and plains (to

mention nothing of the dangers presented by other ζῳα λογον ουκ ἐχων), thought in terms of those sensible elements of the surroundings wherein objectivity and 'thinghood' present themselves indistinguishably in functioning to alert the animal to what is other than itself. These 'alerting aspects' of the experienced world are what the Greeks termed σημεία and modern translators since the Renaissance naively translate simply as 'signs.' They are features of nature which warn us of what to expect (clouds portending rain, omens portending fate and the will of the gods) or what is happening or has happened (smoke warning of burning, milk in the woman's breasts proclaiming her a mother) in the realm of being (see Manetti, 1993–2002).

Yet that is how sign makes its first appearance among the animals as a distinctive element in their awareness of the world. What so appears is not a sign as such, but rather a sensible object *functioning* in a certain distinctive way, namely, so as to make present in awareness (or to point awareness to) something beyond, something other than, the object immediately apprehended. So there are mainly objects that are further signs, all belonging to that great realm of *Φυσις* or 'nature,' the realm of being that, in order to be understood, must come to be λ∈γ∈ται πολλα χως, 'said in many ways.' But for the ζῳα λογον ουκ ἐχων, that is to say, for all the *animalia bruta*, remember, there is no being, only objects, objects distinguished neither from the signs in terms of which they function in structuring perception, nor from the things necessarily involved and incorporated within perception, but unrecognizable as such, as Sebeok (1976: 195) has well described:

> Organisms thus perceive not the *Ding an sich*, i.e., 'things as they are,' but signs, and from these signs, each according to its preexisting *Bauplan*, or blueprint, build up mental models of the world that are equivalent to Peirce's interpretant, the function of which, according to him, is performed by another sign or set of signs that occur together with the given sign, or might occur instead of it. What an animal communicates, in other words, is an edited selection from what, to it, is space/time.

All the ζῳα λογον ουκ ἐχων make use of signs, yet without knowing that there are signs (or, for that matter, that there are 'things' with a being independent of being perceived).

Signs in the World of the ζῳον λογον ἐχων

With the coming of the 'rational animals,' the ζωα λογον ἐχων, signs first appear within the world of objects (as also do 'things'), but not yet (neither signs nor objects nor things) for what they are in their proper being, but only as a certain type or modification of objects. They first appear, as it were, as a certain class of 'things,' 'realities,' namely, those 'realities' that involve such a relation to other objects that to perceive one is to become aware of the other – those objects that are, precisely, σημ∈ια.

We perforce pass over here the 'signs of divination' which, for the Greeks, belonged as much to nature as did the milk in a new mother's breasts (but cf. Manetti, 1993). With that caveat, we can say, with Sebeok (1981: 181), that Greek medicine pertains to the origin of semiotics, as indeed the etymology of the name indicates, so long as we understand that 'semiotics' names a prospective discipline, a 'doctrine' – as Sebeok urged in preference to the expression 'new science' (Sebeok, 1976, 1979: vi; Deely, 1978, 1982: 127–130, 1986) – the proper possibility of which originates in a mode of being (relation as everywhere suprasubjective) that is equiprimordial with the possibility of that general semiosis in nature of which anthroposemiosis is but one of the final, latest specifications, and the one whereby semiosis becomes conscious of itself in the 'metasemiosis' which is what semiotics consists in.

We can say that the ζῳον λογον ἐχων, the first animal able to become aware that there are signs, originally does so only in terms of its sensory awareness of the world of nature and in a confused way, which equates the being proper to signs with a certain functioning exhibited by objects experienced, as it were, as if causally related to specific other objects. These objects are the σημ∈ια, the closest the Greeks of ancient philosophy get to the notion that will actually give rise to semiotics as a general doctrine of signs (in contrast to a branch of natural philosophy or medicine). The Greeks see culture itself as a world of symbols and names, σύμβολα and ονοματα, into which σημ∈ία intrude, and intrude informatively, but do so from another realm entirely.

In terms of what we have come to call semiotics, the Greek theoreticians – from the early Ionian physicists (6th–4th century B.C.) through Socrates (c. 469–399 B.C.), Plato (c. 427–347), Aristotle (384–322 B.C.), and on through the Stoics (4th century B.C.–2nd century A.D.), Epicureans (4th century B.C.–4th century A.D.), and Neoplatonists (3rd–6th century A.D.) ending the ancient Greek age of philosophy in the time of Augustine (354–430 A.D.), and even including Hippocrates (c. 460–377 B.C.) and Galen (A.D. 129–c. 199/225) – are strictly forerunners, *presemioticians* respecting the general doctrine of signs yet to emerge.

Transition to Protosemiotics

Inasmuch as semiotics is the knowledge that arises from the study of the action of signs, or semiosis, an action in

its turn consequent upon the being proper to signs (according to the medieval adage, *agere sequitur esse*, a thing acts according to the way it has being), it is fair to say that, prior to the first explicit awareness of sign as a reality that transcends and is not confined to the realm of nature, semiotics was no more than a remote possibility, a 'science' that, as Saussure (1916: 11) said, "has a right to existence, a place staked out in advance," but no actual existence in the world of intellectual culture. Nor, perhaps, would it fully exist yet, had it not been for the work of Saussure's slightly older contemporary, Charles Sanders Peirce, followed by that master, almost inventor (see Deely, 1989, 2000; Danesi, 2001; Petrilli, 2001; Petrilli and Ponzio, 2001, 2002), of today's quintessentially postmodern 'global semiotics network,' Thomas Albert Sebeok (1920–2001).

Let us sum up the picture so far.

For there to be semiotics there has to be an actual awareness of sign as a general mode of being. The *possibility* of that awareness became part of the earthly biosphere with the emergence of the *ζῳον λογον ἐχων*, but it remained a remote possibility, largely lost in the struggle for survival over a million to fifty million or so years. No doubt ('factually') the awareness that there are signs came earlier; but the first clear records we have of such an *actual* consciousness is still not of signs as any general mode, but rather of signs as a specific and restricted variety of 'natural' phenomenon, the *σημ∈ιον*, particularly as it becomes thematized in the work of Hippocrates (c. 460–377 B.C.) and disseminated among the physicians of the ancient world.

The first record in fact that we have of a thinker proposing a notion of 'sign in general' is Augustine of Hippo (354–430 A.D.), for the purpose of framing his discussion *De doctrina christiana* (397 A.D.). In a sense, then, not before Augustine does semiotics proper begin to emerge as a fully proximate possibility, a nascent reality. For semiotics, as we have said, is the knowledge developed by the study of the action of signs in any realm, and (astonishingly enough: see Eco *et al.*, 1986: 85; cf. Markus, 1972) prior to Augustine we have no reason to believe that anyone thought of an action of signs that extended beyond the natural world to include the whole realm of culture and human language.

This strains credulity, but the present state of the evidence now available (perhaps like the evidence in the time of Aristotle, Ptolemy, and Aquinas that left little or no room for doubt that the earth stood still at the center of the solar, lunar, and stellar revolutions) compels us to consider that Augustine was the first to conceive of sign as transcending the divide between nature and culture, *φυσις* and *ονοματα* – the first to conceive of linguistic communication, and hence the whole realm of cultural *σύμβολα*, which can only be accessed through language, as consisting of signs. On this work and view of Augustine is based the development of the notion of 'sacraments as signs,' or 'sacramental theology,' so central to medieval Christendom (as indeed to Christian churches down to this day). Augustine's definition of sign (as any material structure – natural *or* cultural – that, on being perceived, brings into the perception some other object besides) Peter Lombard will introduce as the opening to the discussion of sacraments in his *Libri Quattuor Sententiarum* (c. 1150), the book that will form the basis for theological study in the universities over the last four hundred years or so of their existence in the Latin Age.

Protosemiotics

Augustine thus marks a divide between the *presemiotic* thinkers of ancient Greek philosophy and the Latin Age, respecting which he stands at the beginning. From this point of view, the point of view of the first or initial proposal of *signum* (or 'sign in general') transcending the opposition of nature to culture, Augustine is not yet fully a semiotician, for he posits rather than warrants; but neither is he any longer a presemiotician. He is, in the expression of Sebeok, a *protosemiotician*, one – the first, in fact – of the pioneers or founding figures of semiotics as such, those thinkers who originally undertook consciously the struggle to establish the essential nature and fundamental varieties of possible semiosis, not as contained within, but as transcending, the world of *φυσις* and *σημ∈ία*.

To get from Augustine to Poinsot and Peirce, then, we have to examine the Latin line of the 'protosemioticians.'

After Augustine will come Boethius (c. 480–524/5 A.D.) among the Latins. He is important to the Latin development of semiotic consciousness, but not directly. I would not even count him formally, but only materially, among the protosemioticians. To the discussion of sign he will no more than presuppose Augustine's point of view and directly contribute nothing. But by his translations of and commentaries upon Aristotle's discussion of *Categories*, particularly the category of relation as an irreducible mode of mind-independent being (*ens reale*), Boethius will lay the groundwork and establish the terminological framework that the Latins will employ in resuming Aristotle's discussion. That discussion resumed, in turn, will lead to the final resolution of the possibility of Augustine's proposal of the notion of 'sign' as a general mode of being. Intermediate to this final resolution will be the 13th-century work of Albertus

Magnus (c. 1201–1280) and Thomas Aquinas (1224/25–1274) establishing the full range of the Aristotelian *corpus* as essential to the curriculum of the newly nascent universities (and against those religious authorities who sought to restrict study to an orthodox canon of writings and to restrict reason to a confessional perspective). The final resolution itself will not be achieved until the early 17th century, when John Poinsot (1589–1644), in his *Treatise on signs* (1632), will be the first to establish both the nature of sign as such in triadic relation (invisible to sense), and consequently the unity of semiotic inquiry in a common subject matter transcending all the possible divisions of sign in particular.

After Poinsot, practically speaking, there will no longer be protosemioticians. Just as after Augustine there could hardly be (at least in the Latin Umwelt) any more simple 'presemioticians,' so after the publication of Poinsot's *Tractatus de Signis* there will only be possible either semioticians proper or instead cryptosemioticians, for immediately after Poinsot's culminating treatise of the Latin development philosophy will begin a new development – modern philosophy – that will move ever more determinately in the direction of an 'epistemology' both ignorant of the doctrine of signs and severed (Schrader, 1967: 188; by the postulate that mental representations as formed by the mind establish the objects of knowledge proportionate only to the biological subjectivity of the knower) from the natural roots of signification as a system of relations interweaving nature and culture. We will examine this interlude in due course. But here we have first to trace the lineage of the protosemioticians.

Poinsot will depend in his work on a long line of Latin thinkers after Augustine: Aquinas (1224/5–1274), first of all; then, in varying manners and degrees, Roger Bacon (c. 1214–1292); Duns Scotus (c. 1266–1308); William of Ockham (c. 1285–1349); Pierre d'Ailly (1350–1420); Thomas de vio Cajetan (1469–1534); Domingo de Soto (1494–1560); Pedro da Fonseca (1528–1599); most proximately the Conimbricenses (1592–1607; they were among Poinsot's undergraduate teachers); perhaps Francisco Araújo (1580–1644); but above all his own genius. For in the end, Poinsot, in a way that no writer before him fully anticipated, hit upon the solution to the problem of how sign can transcend the particular modes of being and weave a web – the semiotic web, as Sebeok (1975) would centuries later say – wherein the whole biological community is caught up in communication by signs even with the inorganic realm of physical nature.

The links from Augustine to Poinsot are direct, but the link from Poinsot to Peirce is indirect, mediated by the Conimbricenses as the source common to both for the doctrine of signs as irreducibly triadic (see Doyle, 1984; Deely, 1994; Beuchot and Deely, 1995). That this irreducibly triadic being proper to signs – that is, constituting every sign as such in its being as sign, and explaining the unique feature of the action of signs whereby semiosis can transpire between what exists and what exists no longer, never did or will exist, or exists not yet but eventually – consists, however, in a *relationship as such*, that is to say, in a mode of being irreducibly suprasubjective as well as triadic, rather than in any particular mode of subjective (or objective) being, such as most theorists prior to Poinsot had assumed (seeing the relation of sign to signified as 'something additional' to or a 'property of' the particular object or thing that was *taken to be* the sign), seems to be the final key element that Poinsot and Peirce hit upon independently. That their sharing in the text *De Signo* of the Conimbricenses a common teacher is a merely coincidental, or even incidental, fact is unlikely in the highest degree. The Conimbricenses provide the common link between the postmodern semioticians after Peirce and the protosemioticians up to Poinsot.

Poinsot marks the terminus of the protosemiotic lineage. It is not that there are no minor Latin figures of his time and after him; of course there are, such as Clemens Timpler (c. 1563–1624), Bartholomaeus Keckermann (c. 1571–1609), Christoph Scheibler (1589–1653), Miguel Comas del Brugar (fl. 1661), the team of Bartholomeus Mastrius (1602–1673) and Bonaventura Belluto (1599–1676), and others. Yet, so far as the development of semiotic consciousness is concerned (see Deely, 1994a), Poinsot's work marks the break between medieval and modern philosophy, on the one side, and stands on the other side as harbinger of the postmodern development wherein semiotics will decisively break with the Kantian doctrine of *Dingen-an-sich* as unknowable (and, by extension, with the Kantian doctrine of empty *Noumena* where human understanding of being turns upon consequences that exceed the capacity of the senses to put to direct experimental test).

Poinsot should stand as the first semiotician. But, as regards what should have been a modern transition from protosemiotics to semiotics proper, his work on signs falls stillborn from the press. There will, instead, perhaps partially as a consequence, be no modern semiotics, strictly speaking; and Poinsot's work effectively will not surface outside its Latin tomb for some three centuries, when it will be resurrected first as an influence in the cryptosemiotics of Jacques Maritain (1938, 1943, 1957; Deely, 1986a), and then in a critical edition as a classic of semiotics in its own right (Poinsot, 1632/1985; see Sebeok, 1986a).

Two Watershed Events

Ideally, we should here go through, one by one, the doctrines of the several protosemioticians between Augustine and Poinsot, such as Peter Abaelard (c. 1079–1142), Petrus Hispanus (c. 1210–1277), Roger Bacon (c. 1214–1292), John Duns Scotus (c. 1266–1308), William of Ockham (c. 1285–1349), Pierre d'Ailly (1350–1420), Dominic Soto (1494–1560), Pedro da Fonseca (1528–1599), the Conimbricenses (i. 1592–1607), Francisco Araùjo (1580–1644). I have outlined details of this path elsewhere (Deely, 1998, 2001: chs. 6–10). Here I will consider simply the watershed events of this Latin development of semiotic consciousness. With the consideration of Augustine, there are mainly two such events. There is a third, of course, but when that one arrived the *de jure* standpoint proper to semiotics became fully achieved in principle, for the third watershed was the arrival (first in the work of Poinsot, then in the work of Peirce) at explicit, thematic consciousness of the uniqueness of the being at the heart of signs which enables them (to use the medieval terms) to transcend and to coordinate in human science the otherwise disparate orders of *ens reale* (mind-independent being) and *ens rationis* (mind-dependent being) and to explain their synthesis in (to use the modern term) the 'social construction of reality' (Berger and Luckmann, 1966).

Augustine's genius was to see that the sign transcends the divide between nature and culture. That is the first watershed. Augustine marked the terms of this divide with respective labels *signa naturalia* ('natural signs') and *signa data* (including 'conventional signs'). It was a little oversimplified (Poinsot would show that conventional signs are a matter of custom as well as stipulation, and so, along with other later Latins, would divide the social signs within human culture into *signa ex consuetudine*, which give a continuity to nature and culture in patterns of behavior assumed and presumed natural, and *signa ad placita* strictly so called, that is to say, conventional signs where the element of stipulation remains fully in the foreground, however layered-over habit would try to make it). But Augustine's reduction of σημ∈ία to a subclass of signs (*signa naturalia*, in Augustine's terms) subordinate to *signum* in general and coordinate with conventional signs (within *signa data*) as a species served the introduction of the consideration of sign as a mode of being transcending particularity.

The second watershed remains partly concealed to our eyes, so far as to whom originally to attribute it. It is anticipated in d'Ailly; in Soto, who clearly got it from his studies among the nominalist professors of Paris at the 15th–16th century transition, the terminology appears full-blown. In any event, whoever marked the terms of the divide of this second watershed with the respective labels *signa formalia* and *signa instrumentalia* did no small service to the Latin development of semiotic consciousness, for what he or she opened the way to was nothing less than the realization that the psychological states of animals (whether λογον ἐχων or λογον ουκ ἐχων) are alike in serving first of all *ex natura suarum* ('according to their very nature') the function of presenting what is other than themselves in this or that light ('under this or that interpretation,' as we might say). Psychological states, now newly designated 'formal signs' in contrast to objects of perception labeled 'instrumental signs,' the Latins more generally called simply *passiones animae*, 'passions of the soul.' They are not directly detectable by sensation ('external sense'), but they are determinative of perception and, in intellection (for the ζῳα λογον ἐχων), of understanding as well.

To make of the *passiones animae* 'signs' on a par with σημ∈ία and *verba* (ονοματα) is no small thing. To speak of σημεία and ονοματα as signs was a watershed, because it made the 'theory of signs' transcend the division between nature and culture. To speak now of the *passiones animae* as well as the *verba exteriora*, the spoken words of human language, as 'signs' now makes that nascent 'theory' of sign, unheard of among the Greeks, transcend further the division between inner and outer. What is 'in the mind' and what is 'outside the mind' are now alike united in the being proper to sign!

It was no mean proposal, some two centuries or so after Aquinas laid the foundation which Poinsot would demonstrate for a unified doctrine of signs.

The Role of Thomas Aquinas

Aquinas plays a crucial role in the establishment of semiotics as the foundation of the possibility of sciences as species-specifically human modes of understanding, but not the decisive role. It could have been otherwise, for no one in the Latin Age treated more profoundly of the passions of the soul, or treated more extensively of the teleonomy of those passions toward the being that surrounds the ζῳον λογον ἐχων as its environment. But in fact Aquinas never focused on the point, never thematized the question of what is the being proper to signs that enables signs to exhibit an action that transcends nature and culture, inner and outer. What he does do, however, is to bring explicitly to the foreground the incompatibility between the definition of sign in general that Augustine proposed and the being proper to signs that enables it to function as it does in mediating the

difference between objects and things (objectivity, on the one hand, and mere physical existence on the other). In bringing fully into the Latin consciousness this inner tension between Augustine's proposal of sign as a general mode of being and his attempt to define that mode, Aquinas creates the texts (see Deely, 1994b: 58 n.9) that provide the proximate materials for Poinsot's synthesis establishing the foundations in relative being for the doctrine of signs as a subject matter in its own right – in short, for semiotics in the full and postmodern sense. But Aquinas does not himself thematize or even directly focus upon, let alone resolve, this incompatibility, this "burning and inevitable problem" (Beuchot, 1986: 26) bequeathed from Augustine, concerning the being proper to sign.

'Die Spur des Zeichens'

The one who sets the complex discussion of Aquinas's day on what will prove 'die Spur des Zeichens' (Meier-Oeser, 1997), however, seems to have been Roger Bacon (c. 1214–1292), a rather bitter figure whose attitude is well summed up in his self-description ([1292] 1988: 12): "the only seer in the land of the blind." For a seer – let alone "the only seer" – Bacon in the end turned out to be pretty blind, at least in the matter of semiotics (Deely, 2001: 367–368), as also in the importance of separating the confessional use of reason (*sacra doctrina*, or theology in Aquinas's sense) from the philosophical use of reason or, as we might also say (in view of the scientific developments Bacon presaged but Galileo especially introduced), 'reason *tout court*.'

The Conimbricenses it was (see Doyle, 1984, 2001), after Aquinas, who finally provoked Poinsot to the daring perspective he outlined in his *Treatise on Signs*. After Poinsot's achievement, as I have pointed out, there could no longer be 'protosemioticians,' but only either 'cryptosemioticians' made such by ignorance (far from culpable, we may generally say on the early moderns' behalf, given the debacle of the trial of Galileo in 1633; and, be it added, followed by Descartes's *Meditations on First Philosophy* in 1645) or 'semioticians' – 'semiotists' full-blown. As Peirce was 'the last of the moderns and first of the postmoderns,' so Poinsot was the 'last of the protosemioticians.' But I would have to say that, unlike Peirce, he was not quite 'the first of the semiotists.' Like Moses in Old Testament times, he was destined to 'see but not enter' the Promised Land. Eyes fixed firmly on the past, the inevitable future was just not his center of interest. In essaying his *Tractatus de Signis*, as in the whole of his philosophical and theological writings, I think, Poinsot did exactly what Simonin (1930: 145–146) described him as doing: he attempted a 'synthesis of irreconcilables.' For while he sketched for future thought the requirements for the development of tradition, he yet made of the established tradition, as it were, a Procrustean bed on or against the horizon of which to present the requirements of future developments, as though those developments were to be recognized, indeed, in their consequential inevitablity, yet without being allowed to introduce changes in the patterns and methods of the thought that preceded them and made their difference originally visible.

The Third Watershed

Even so, it was Poinsot who showed that distinctively human and scientific knowledge is possible because the human mind is able in principle (certainly not always in fact, to be sure) to discriminate between true and false in its apprehensions, and is able to do this by discriminating between signs and objects, on the one hand, and objects that are and are not also things, on the other hand. Presupposed to the whole enterprise of separating the true from the false, the fictive from the real, the cultural from the natural, he showed, is in every case *the action of signs* or 'semiosis' (in Peirce's later term), rooted in the indifference of relation as such (in which the being of all signs suprasubjectively consists) to whether its provenance is mind-dependent or mind-independent, as determined by circumstances surrounding the sign (which it is the task of the cognitive organism to determine, after all!). The prior possibility of finite truth at all, Poinsot showed, lay in the being unique to relation; and the possibility of truth as correspondence lay in the fact that circumstances external to any relation determine whether that relation belongs to the order of mind-independent being (*ens reale*) or mind-dependent being (*ens rationis*). Both these orders are alike determinations of that *ens primum cognitum* which distinguishes the animals *λογον ἐχων* from the animals *λογον ουκ ἐχων* in the first place.

It is because signs are not sign-vehicles (Deely, 2001a), and sign-vehicles are the particulars they are (namely, sign-vehicles as opposed merely to objects) only because of the particular place they occupy (or 'role they play') within the triadic structure of the relation that constitutes a sign strictly and properly, that signs at once "perfuse the universe" (Peirce, 1906: CP 5.448n; Deely, 1997) of all animals alike, *ζῳα λογον ουκ ἐχων* (*animalia bruta*) and *ζῳα λογον ἐχων* (*animalia rationalia*), and constantly trade places with objects and interpretants in the dynamic context of everchanging experience (the "spiral of semiosis," as I have put it: Deely, 2001b: 28, 2003a: 164). More particularly, because signs as such, strictly and properly speaking, *consist in* and do not merely *involve* triadic relations, and because relations as

such (as distinct from the objects and/or things *involved* in the relations) are indetectable by sense in any direct manner, the human animal (the ζῳον λογον ἐχων) is the only animal that not only necessarily makes use of signs but contingently is able to become aware that there are signs and, beyond that confused awareness, to become further aware of what signs are in their proper being, namely, triadic relations as such knowable but not directly perceptible.

This was the third and final watershed in the development of semiotic consciousness. To see that the sign consists in a triadic relation is to see *why* it transcends nature and culture, inner and outer: because it is suprasubjective respecting the whole order of subjective being, psychic no less than physical, even though, like every relation, triadic or dyadic, it cannot exist apart from those subjectivities and objectivities it fashions into a historical world, through zoösemiosis or also anthroposemiosis, as the case may be.

The Cryptosemiotic Interlude

The point of view introduced into and distinctive of modern philosophy is often characterized as 'the epistemological turn' (much later, and more narrowly still, 'the linguistic turn'), an expression that means, concretely, the point of view introduced into philosophy by Descartes and furthered, with differing emphases, by Locke and Hume after him, but synthesized by the work of Immanuel Kant (1724–1804) transcending and reducing to order the early modern opposition between Rationalism (after Descartes, 1596–1650) and Empiricism (after Locke, 1632–1704).

From the point of view of semiotics, however, especially if we go back to its origins in the general notion of sign, the modern standpoint, whether epistemologically or (a fortiori) linguistically conceived, is itself highly problematic. For I deem it is clear by this point that, to reach all the way from Augustine to Poinsot, to say nothing of Peirce after Poinsot, we have had to adopt and fashion a perspective on being and the being of signs that is considerably broader than any such modern perspective, early or late (pre-Kantian or post-Kantian), can supply. Fortunately, semiotics, in sharp contrast to semiology in its original 20th century development (Sebeok, 1977), being of the essence of postmodernity (Deely, 2004a), depends little if at all on late modern perspectives for its self-understanding (cf. Bouissac, 1981; Deely, 1982: 3). Further, semiotics, when speaking from the vantage proper to itself, derived from the being distinctive of sign as transcending from the first (Poinsot, 1632: Book I, Question 1, 117/18–118/18) the modern realism/idealism opposition, has a very precise, though generic, understanding of 'science' as a species-specifically human possibility that antecedes even philosophy itself, let alone the later sciences to which anthroposemiosis gives rise. For all the sciences, humanistic or natural, and the doctrinal philosophical ones no less than the experimental and mathematicized modern sciences, have in common their origin in the ability of human understanding to consider objects of experience in terms of a question as to whether any given object or range of objects simply reduces to our experience of it, or exhibits as well a being which obtains independently of (and whether prior or posterior to) the experience in which the objects in question are given as objects.

One-sided and crippled as philosophy becomes in taking the modern mainstream 'epistemological turn,' however, it is not without its contributions to semiotics proper, even though these contributions are perforce 'underground,' as it were, and in spite of the solipsistic constraints that accompany the 'epistemological turn.' History has its many ironies, and not least among them is the fact that the quintessentially modern Kantian perspective has inspired the single most important foundational work for biosemiotics, and especially for zoösemiotics (Sebeok, 1976, 1979), namely, the *Umwelttheorie* of the cryptosemiotician Jakob von Uexküll (Kull, 2001; Deely, 2004). On the other hand, the Kantian perspective extended to anthroposemiosis introduces a crippling erasure (cf. Pieper, 1952: 84–85; Deely, 2004), namely, the denial to human understanding of the ability to investigate the things themselves in themselves as they provide an environment that is common to all the species of life on earth.

This last remark is not made lightly, for it is not yet generally understood how completely the Kantian perspective is opposed to the original foundations of semiotic inquiry as proposed by Augustine. It is not too much to say that the difference between anthroposemiosis and zoösemiosis turns upon bringing out from under the erasure in which Kant placed it the medieval notion of *ens reale*, developed from the original philosophizing of ancient Greece aimed at ον. *Ens reale* is the notion of being as existing independently of human awareness and knowable in the independent requirements and exercise of that existence, something that natural science today presupposes, especially in the increasingly important applications of science to environmental matters (and something that modern science presupposed from the beginning of the establishment of its difference in matters 'epistemological' from what modern philosophy tried to require in cutting off the whole realm of *ens reale* from the sphere of the knowable: see Deely, 1984, 2001: ch. 13, esp. 553–572).

In tracing the history of semiotics from Poinsot to Peirce, therefore, we cannot draw a straight line, as it

were, nor can we adopt, let alone immerse ourselves in, the standpoint of the 'epistemological turn' which modern philosophy so intimately involves, but which in its very adoption required an abandonment of the Way of Signs in favor of what ultimately proved, on its own terms, a cul-de-sac: the Way of Ideas, reducing and subordinating signification to representation.

In the historical evolution of human intellectual culture, while human animals by virtue of their intellectual nature spontaneously recognize the reality of things existing prior to and independently of themselves in a surrounding environment, in the very doing so they overlook the profound difference between things as objects and those same things as things. Human animals tend to treat as nothing the more general difference between objects as such and things as such, as though to speak of 'objects' and to speak of 'things' – as in English to this day – were a matter of indifference and virtual equivalence. This is a theoretical oversight of the first magnitude, to be sure, and it is to his merit that Immanuel Kant set himself to remedy the situation. But, as it turned out, Kant's version of a cure works only when adapted for our understanding of zoösemiosis (a large part, but not the whole, within anthroposemiosis). Applied to anthroposemiosis as a whole, the cure proved worse than the disease, because the Kantian view of the relation of reason to sense eliminates the very factor of being that anthroposemiosis introduces into the otherwise purely animal Umwelt!

What Kant failed to see, and the moderns before and after him as well, was the hard-won insight of the original semiotic consciousness that objectivity presupposes semiosis (see "A new definition of *signum*" in Deely, 2001: 434–435), and this semiosis is already prior and indifferent to the difference between objects as such and things, precisely because it is presupposed to the recognition of either and both of them. Kant saw the need to remedy a blindness species-specific to the ζῳον λογον ἐχῶν, but he prescribed the wrong remedy. Small wonder, then, that in his account of 'epistemology' signs hardly entered the picture, even while invisibly playing their indispensable role nonetheless in mediating between things and objects, on the one hand, and among objects, on the other. Small wonder too that, on Kant's account, what semiotics would establish as the being proper to signs, namely, relation in its indifference to the opposed orders of *ens reale* and *ens rationis*, was ruled out of account *a priori*.

Semiotics Proper

Semiotics thus, as it developed from Augustine to Peirce (and especially as it was definitively illustrated in the work of John Poinsot, intermediary between the age of the protosemioticians after Augustine and the semioticians after Peirce), established nothing less than the foundation for understanding the distinctiveness of anthroposemiosis, the action of signs among human animals, ζῳα λογον ἐχῶν, the very possibility of 'scientific understanding' in whatever area. The *Treatise on signs* of Poinsot exhibited that semiotics was, of its very nature as defining the interface between nature and culture, already more than modern philosophy with its 'epistemological turn' could accommodate. Semiotics was from the start the quintessence of postmodernity, given what modernity became (or turned out to be) in the works of 'rationalism' and 'empiricism' synthesized by Kant. And this is what Peirce too arrived at in his own development of a semiotic consciousness, drawing from the source he shared in common with Poinsot – the Conimbricenses, and, more generally, other Latin protosemioticians which Peirce distinguished himself among the moderns by studying.

What the postmodern semiotic development – the actual development of semiotics proper, as distinguished from simply achieving the standpoint from which such a development becomes possible – finally made clear was the fact, not yet self-evident in the days of the protosemioticians, and even less so in the time of presemiotics, that, as Thomas Sebeok (2001: ix) put the matter in his final book: "each and every man, woman, and child superintends over a partially shared pool of signs in which that same monadic being is immersed and must navigate for survival throughout its singular life." Therein lies the semiosic foundation for anthroposemiosis itself, of which all the sciences, past, present, and to come, are, with all their semiotic dimensions, but offshoots. That is the point at which the history of semiotics stands as the 21st century opens upon the postmodern dawn of a global intellectual culture.
